In the throat difficulties, the result of contracting a cold, especially tonsilitis of an acute nature, whether a simple or ulcerated case, the local symptoms in the way of pain are always such as will command attention at the outset of the disease, the degree of fever existing also is such as would, in the majority of instances, cause the inexperienced physician to have much concern for the welfare of the patient These conditions are worthy of note in the differential diagnosis of diphtheria and acute tonsilitis, the result of cold In the former, the local inconvenience and the general or systemic disturbances are not in degree at all in keeping with the dangerous character of the disease The tendency of the disease, being toward a rapid fatality when not treated, and often so when not treated timely and efficiently, while in the latter, the local inconvenience and general symptoms are in severity altogether out of keeping with the slight dangers of the disease, the tendency being even without treatment toward recovery

Is membranous croup and croupal diphtheria, (not diphtheritic croup, because there is no such disease,) one and the same disease? Difference of opinion still exists in regard to these two diseases, or as some

believe, in this *one* disease Properly there is no such disease as diphtheritic croup, but it is diphtheria of a croupal type inasmuch as it involves with in in flammatory condition and an exudation, the larynx, the same organ affected as is the case in simple or spasmodic croup, and yet the germ or cause of diph theria and the cause of spasmodic laryngitis, differ more widely than day and night In spite of this the nomenclature is simple laryngitis, membranous laryn gitis and diphtheritic laryngitis, the former two are correct, but there is no such disease as the latter would indicate, the *disease* not being indicated by the *part* affected but the *type* of the disease being indicated by the part affected, hence, what is com monly called diphtheritic croup should be called and is intended to mean, croupal or laryngeal diphtheria Believing that membranous laryngitis is a separate and distinct disease from laryngeal, or any other form of diphtheria, I will refer briefly to a few differen tial symptoms or conditions In simple or spasmodic laryngitis the attack is sudden, no exudation, with or without severe fever, first paroxysms most severe, at tack much abated in twenty four hours In mem branous laryngitis, attack sudden, similar to that of simple laryngitis, laryngeal symptoms, after first paroxysm becomes more severe, paroxysms become more frequent and a constantly increasing dyspnœa exists, pulse and temperature also gradually become higher, there is never any exudation upon the pharynx or tonsils, and there never exists the odor so char acteristic of diphtheria, whether it be of laryngeal, pharyngeal, or nasal variety The symptoms of a fatal case are gradual asphyxia, with exudation in the finer bronchial tubes and exhaustion from prolonged high temperature, the result of acute inflammatory conditions of prolonged duration, having continued a week or more No signs of systemic contamina tion, the patient dies exhausted

In croupal diphtheria the patient is indisposed, a general malaise existing for a matter of twenty four hours, he becomes gradually hoarse and respiration becomes more and more difficult There is a strik ing absence in the frequency of the spasmodic coughs so common in laryngitis, of either variety The temperature and pulse are not, as a rule, higher than in the ordinary types of diphtheria The breath is characteristically offensive, there are always found patches of exudation upon the tonsils or pharynx, usually of a button like form, the patient sinks rap idly, usually perishes in from four to six days, not from asphyxia, but from blood-poisoning, with all the symptoms so characteristic of the laryngeal type of diphtheria I give below an extract from a letter re cently furnished by myself, relative to an outbreak of diphtheria in our city during the year 1886, which may be of some interest in connection with this paper

There were reported during the year 1886 ninety one cases of diphtheria In some instances, through misunderstanding or neglect, reports were made of the existence of the disease but once in the same family, although cases subsequent to the first one occurred, and in this manner it is probable that some of the cases reported as diphtheria were cases only of ulcerated tonsillitis It is safe, however, to esti mate that there occurred during 1886, something like 100 cases of diphtheria There were reported deaths caused by diphtheria during 1886, 41, as follows

January—1 male, æt 4 years
February—1 male, æt 1 year
March—1 female, æt 7 years
July—1 female, æt 3 years
August—Males, 3, æt 1, 1 and 10 years, 1 female, æt 6 years
September—Males, 4, æt 7, 7, 8 and 10 years, 3 females, æt 10 months, 2 and 2 years
October—Males, 7, æt 1, 2, 2, 3, 5, 8 and 9 years, females, 6, æt 1, 3 3, 3, 6 and 6 years
November—Males, 2, æt 3 and 12 years, females, 5, æt 8 months, 2, 4, 4 and 4 years
December—Males, 2, æt 3 and 5 years, females, 4, æt 1, 2, 7 and 9 years Total—Males, 20, females, 21

Average age of males, about 5 years and 2 months, average age of females, about 3 years and 8 months, the difference in the age as between male and female being about 1 year and 8 months Males the oldest It will be seen by table, that of those who died only about one third, or 33⅓ per cent, were school chil dren It will be further seen by table that the dis ease increased in August, and reached its maximum in October, and diminished in November and De cember in about the same ratio as it increased in August and September Various questions suggest themselves as regards the abatement of the disease, among them Did we find an obstructed sewer? Did we find an impure water supply? Did we close our public schools? No, we found nothing, changed nothing, and did not close our schools The disease seemed to come with the winds and vanished with them Had we made notable changes in water sup ply, or sewage, or closed our schools at a moment when the disease was at a maximum, and the abate ment then occurred which *did* occur from unknown causes, all interested would have been unanimous in declaring that the cause of the disease in this local ity had been found and removed During a given week in October occurred the greatest number of cases and the largest fatality, and during the week following, there were reported only a few cases So striking was this, I remember remarking to a mem ber of the School Board "If you had closed the schools last week with a view of breaking up the diphtheria, and not yet reopened (a week later), all the city would have been unanimous in declaring that you had done just the right thing to arrest the disease"

For a time it seemed the cause of the disease ex isted in well water, all cases occurring in families who used well water When, however, cases oc curred in families who were using river water, this idea was promptly abandoned What caused the disease and what abated it are questions of interest We understand that the disease is, when once devel oped, easily communicated to other individuals by direct contact, mainly through respiratory passages, but inasmuch as our schools were not closed, this possible (not probable) source of communication was not and is not now removed

Our hygienic surroundings, water, sewage, etc, except as affected by frost, remain the same, and yet the disease has substantially vanished from our midst What, then, has caused diphtheria among us? Diphtheria is classed as among the diseases due to faulty hygienic surroundings or filth My own explanation of the matter is that in filth exists and may be found a factor in the development of diphtheria, but that, in order to develop the disease from these sources, there must exist certain atmospheric influences which, coupled with tangible impurities, develop the disease, but that the disease *is not* and cannot be developed by either of these factors alone

Admitting the nature of the disease to be of rapid course, requiring to be met promptly with remedies which will destroy germs and remedies which will support and sustain the system, the question remains, what remedies are best adapted to accomplish the desired results? In the way of drugs proper, two remedies above all others quinine and tinc chlor of iron I am well aware that these are not new remedies, and I am equally well aware that the profession have not, at least until recently, attached to these remedies the importance which they merit It is generally admitted and unquestionably demonstrated that quinine is a specific in the destruction of malarial germs, and if I have seen the good effects of quinine in malarial disease I have seen equally good effects in diphtheria, and believe that when it has failed it was under circumstances where the system had already become so overwhelmed with the disease that *no* remedy could be properly carried into it, or that it was not properly administered It should be remembered that, in treating malarial disease, it will recur and wait for the remedy a matter of weeks, and then yield promptly This is not the case in diphtheria The patient must have full doses, an adult, the first dose 15 or 20 grains subsequently 10 grains every 6 hours during the first 36 or 48 hours, after this the dose should be such as will continue a slight ringing in the ears Care should be taken to guard against overdosing with quinine in diphtheria, since in large and continuous doses it probably acts as a depressment upon the nerve centres, the disease itself having the same tendency, it is important to be cautious at least The effect of quinine would be in the first place as a direct germicide, and in the next place under the class of fortifiers, so altering the character of the blood as to make it proof against the inroads of diphtheria germs It may also be considered a fortifier on account of its general tonic properties such as are obtained when given in small doses

Tinc of chlor of iron may be used locally as a direct germicide and constitutionally as a fortifier by preserving the purity of the blood and nutrient qualities, possibly also having germicidal effect through the blood How shall it be used? As a local application, in varying strength, from 1 part of iron to 3 of glycerin and so on to full strength, as the case in the judgment of the physician requires Applications should be made twice or three times in twenty four hours by the physician (*never* entrusted, if it can be possibly avoided, to parent or nurse), because they never will even *half* do the work, failing partly from sympathy and partly for want of experience Twenty drops of the muriated tincture should be given an adult in a teaspoonful of water every two hours so long as the stomach will bear it, if the stomach becomes irritable then the interval must be lengthened It is not amiss to call attention here to the fact that chlorides of various kinds have been and are recommended in the treatment of this disease Their virtue, if any they possess, is probably due to direct germicidal properties, and also the second class of fortifiers As a solvent of membrane, fumes of slacking lime are among the most valuable applications, whether the attack be one of laryngeal or other type Hot applications I believe to be always injurious, predisposing to the more rapid development of the disease germs Ice may be taken frequently in the mouth and allowed to dissolve, when desired by the patient Stimulants must be given in full doses, whiskey, brandy, or wine, as may be indicated or as the patient may prefer, at the approach of symptoms of prostration Many other remedies might here be discussed, suffice it to say, that all remedies having properties and qualities identical with the properties of the remedies here recommended may be substituted, and that *all* remedies which have a depressing effect upon the system should be cautiously administered, and no physician should trifle with this disease This feature in the treatment of diphtheria should be ever remembered by the physician, that to insure success, in all cases, you must insist that medicines, stimulants and food be given on the hour, night and day, and that all local applications should be made by the physician, and not entrusted to parent or nurse

To show the importance of this thoroughness and the necessity of promptness in treatment, I will cite the circumstances connected with the occurrence of the disease in a family of ten persons, father, mother, four children between the ages of 6 and 12 years, and four children (three sons and one daughter), between the ages of 17 and 25 All but the father contracted the disease I was called in consultation when all had contracted the disease The mother, adult daughter and two adult sons had already died, and one other son was in a dying condition (all happening within a period of two weeks), the children under 12, four in number, all recovered The treatment adopted was the same for children and adults Why did the adults die and the children recover? Because the adults refused to have any treatment until the disease had far advanced, and the children were forced to treatment early

HYDATIDIFORM MOLE

Read before the Medical Society of the District of Columbia, September 23, 1887

BY THOMAS C SMITH, M D,

OF WASHINGTON, D C

Hydatidiform degeneration of the chorionic villi is an unusual disease, but it is not so rarely met with

as might be inferred from the experience of Madame Boivin, who "saw but one case in 2,375 deliveries" (Parvin) I have met with two cases, that I think are sufficiently interesting to place on record The second in chronological order will be first narrated, and is as follows

Mrs F , white, nearly 20 years of age, was married April 11, 1887, menstruated April 17, and again May 17 In June the menses failed to appear and the usual symptoms of pregnancy shortly supervened Nausea and vomiting were almost incessant up to the time of my first visit, Sept 15, 1887 The mammary glands had, also, increased in size, and the pigmentation of the areola was well marked Early in the morning of Sept 15, the lady was taken with pain and hæmorrhage, and when I arrived at her house she was flooding profusely Examination revealed the uterus enlarged and reaching to the umbilicus, and quite hard to the palpating hand On making a vaginal examination the os was found to be closed, but the blood was flowing freely Believing miscarriage to be impending, and from the quantity of blood lost, not to be prevented, the vagina was tamponed, and the patient given ergot and opium The patient believed herself to be four months pregnant, while the size of the uterus indicated that she was at least six months advanced in gestation Four hours later the condition of the patient was practically unchanged She was still flowing freely and the pulse was quick and weak The tampon was removed and the cervix still found undilated The vagina was again packed with absorbent cotton, and the same medicine continued In the evening there had been no flow and the patient expressed herself as being comfortable At 11 o'clock at night I was again sent for and found the patient in great pain and losing some blood The tampon was removed and the os found to be open and dilatable, so that the index finger was readily passed into the uterus where it encountered a mass which felt like an aggregation of dense cobwebs Owing to the sensitiveness of the abdomen, the patient could not tolerate sufficient pressure to enable me to force the uterus down far enough for the finger to clear out the contained mass, and it became necessary to administer ether, after which the hand was passed into the vagina, and the finger in the uterus broke down the diseased tissue, and on removing the hand the uterus promptly contracted and extruded such of the growth as had been detached It was necessary to introduce the hand several times, and then I had the satisfaction of finding the womb entirely empty The hæmorrhage ceased, but ergot was given to secure firm contraction The lady has completely recovered except from the anæmia which ensued on the loss of blood

It may be stated here that at no time during the pregnancy was there any bloody or watery discharge from the vagina previous to my visit

The quantity of currant and grape like bodies removed from this lady was about a quart Many were detached singly, while others were in clusters and adhering to the parent tissue

The other case that came under my treatment was that of a lady who had borne two children, and who believed herself to be again pregnant When I was first called she was having some flow of blood from the vagina, but as the os was not dilated I endeavored by rest and suitable treatment to prevent what appeared to be an attempt to miscarry This effort proved effective at the time, but hemorrhage recurred during the following six weeks and finally, on finding the cervix dilatable, the hand was passed into the uterus and not less than a half gallon of hydatidiform bodies removed The anæmia in this case was very great, but the lady entirely recovered I have since delivered her of two children This case occurred over six years ago and is reported from memory, but in conversation with the patient a few days ago she verified the history given above

The cystic bodies from the last mentioned case were generally much larger than those presented this evening

I have found the study of the disease under consideration a very interesting one, and will give a brief summary of the points worth noting

It is now universally conceded that the affection is due to a proliferative degeneration of the villi of the chorion Formerly no distinction was made between the true hydatid and the cysts found in the disease under discussion To Cruveilhier is due, I believe, the credit of demonstrating the difference between the conditions

The time at which the chorionic degeneration commences and the exciting causes are questions of interest The weight of opinion, however, is that the disease necessarily begins within the first three months of gestation Thomas sufficiently elucidates the matter when he says "It is probable that after the end of the third month no such degeneration can occur in the secundines—for after that period the placenta is formed, the villi which existed at its site become vascular, and those over other parts of the surface of the fœtal sac undergo atrophy It is true that at the period of parturition, masses of these sacs have, in rare instances, been expelled, but in such cases it is probable that some portion of the chorion had begun to degenerate at an early period of conception" Dr Graily Hewitt dissents from the generally accepted opinion that the starting point of the disease is disease of the chorion, and endeavors to show that the degeneration is the result of the death of the embryo, but this view is apparently refuted by the fact that the disease may continue until the completion of gestation and the birth of the living child But the fact that in twin pregnancy one fœtus may be carried to term, while the chorion of the other may degenerate and be cast off at the time of parturition, or later, lends plausibility to the explanation given by Hewitt

And the fact that moles may be retained for an indefinite period, is an important and far reaching one, and the necessity of admitting and recognizing it has been seriously insisted upon, as the character of women may be assailed unless that is done Thus a woman may cast off a hydatid mole long after the death of her husband, or a child may be born at term and months afterward a mole may be discharged

If this should happen during the absence of a husband the character of a wife might be smirched More than one authority has directed attention to this matter

Disease of the endometrium, it has been claimed, may be a cause of hydatid degeneration of the chorion, but it is only mentioned to direct attention to the subject

The query has been propounded, whether a portion of placenta retained at the full term can take on hydatidiform change? Some have answered in the affirmative, (Montgomery and Ramsbotham) but all recent writers dispute this conclusion

Another interesting fact is that the degeneration of the chorion may occur in successive pregnancies Tait instances the case of a woman who had this occur five times, and who at the time he wrote was again pregnant, but without showing signs of the disease

Concerning the symptoms of hydatidiform degeneration of the chorion, it may be said that there are but few that are characteristic of the disease Rapid development of the uterus is the sign most generally present, but the patient is generally too ignorant of the subject to consider the meaning of the enlargement, and the physician, when called to the case, is so prone to believe that the woman has made a mistake in her reckoning, or is deceiving him to cover up her misdoings, that he pays little attention to it until the degenerated mass has been expelled Still, this is an important symptom, for it is conceded by all that the uterus is enlarged far beyond the size it should have attained if the period of gestation is correctly given by the woman In my patient the enlarged uterus reached the umbilicus, but according to her story she could not have been quite four months pregnant when the diseased mass was thrown off Attacks of hæmorrhage, or of bloody and watery discharges recurring at intervals, are relied on for aid in diagnosis One of my patients had this symptom, the other not Expulsion of vesicles would be characteristic if they were found on examination, but the symptom is too often absent Other signs are irregularity in the shape of the uterus, absence of fœtal heart sounds and of fœtal movements, enlargement of mammary glands but no pigmentation of the areola, according to Bedford, but there *was* pigmentation in my case, and in my opinion it ought to be found for the pre-existence of pregnancy is a *sine qua non* to the development of the diseased state under discussion Meigs says, "Intense constitutional irritation accompanies hydatid pregnancy in those examples of it where the growth is violently rapid "

The symptoms then to be relied upon according to Depaul, are 1 Rapid development of the uterus 2 Attacks of hæmorrhage 3 Expulsion of vesicles

The prognosis is usually favorable, but exceptionally the proliferating bodies develop so as to enter the uterine sinuses, thereby producing great thinning of the walls of the womb which favors rupture of the uterus and discharge of its contents into the peritoneal cavity Tyler Smith once saw a case in which the uterus had been ruptured by the violence of its contractions in expelling a hydatid mole But the greatest danger is from hæmorrhage and its sequalæ —shock and anæmia Lusk reports a case of death in a patient of his from this cause

The *treatment* of these cases will be mainly applicable to miscarriage If the hæmorrhage is slight and the os uteri closed, rest and opium will meet the indication For severe hæmorrhage, use the tampon until the uterus dilates or is dilated by any suitable method, and remove the offending material with the finger The hand should be introduced into the vagina to facilitate the emptying of the uterus, after the patient has been etherized

---

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS —(See the preceding numbers of THE JOURNAL) 24 In regard to the treatment of tuberculous affections of joints, I believe that parenchymatous injections with a Pravaz's syringe (of tincture of iodine, carbolic acid, sublimate, arsenic, etc) have thus far given no results worth mentioning Puncture of the joint with a large trocar (an abdominal trocar), and subsequent washing out with disinfecting and other solutions, is effective only in exceptional cases (Hydrops tuberculosus, etc) In regard to operative procedures, the following are to be considered

a Incision (and where possible double incision) *and drainage*, with or without scraping out the joint with the sharp spoon (Arthrotomy)

b Total extirpation of the capsule of the joint, making a large incision as when opening the joint for resection, leaving the bony epiphyses and articular cartilages (Arthrectomy or arthrectomia synovialis)

c Resection of the joint, with simultaneous extirpation of the capsule of the joint, but always leaving the healthy parts of the bones, and often making only partial or at least atypical resections (Arthrectomia ossalis et synovialis)

The former operation of leaving the gravely diseased "fungous" capsule of the joint, and simply decapitating the articular end of the femur and humerus, without complete and thorough cleansing out of the socket, should be abandoned

As to the use of the sharp spoon it should be remembered that with it those inter-muscular, periarticular, and subcutaneous abscesses communicating with the diseased joint or osseous foci, and which are lined with a characteristic and easily detached membrane, can be completely cleansed of all tuberculous granulations, furthermore, the sharp spoon proves sufficient in the case of bone, as we can scrape out the most diseased tissue, down to the healthy spongiosa, but this is impossible with a tuberculous degenerated synovial membrane An abscess membrane, easily detached from healthy tissue, does not exist in this case, and the tuberculous granulations here infiltrate the fibrous layers of the capsule Thus it is that after the use of the sharp spoon recurrences easily exist, when the synovialis was severely affected In using the sharp spoon the

operation should be bloodless and done with large incisions, which permit a complete view of the field of operation, then follow the operation with careful antiseptic disinfection and after treatment

25 Tuberculosis of bones without affection of the large joints is represented clinically by the following forms of disease

a *Spina ventosa* (Padarthrocace) ampullaceous thickenings of the phalanges of the fingers and toes, sometimes of the metacarpal and metatarsal bones, exceptionally of the ulna and radius, or even of the tibia and femur usually multiple, and depending on a tuberculous osteomyelitis The affections is seen only in children, in their early years, and gets so completely well, in spite of its multiplicity, often without breaking, suppuration or the formation of sequestra, that no deviation in the shape or growth of the affected bone remains afterwards

b Tuberculous suppuration and necrosis of the orbital portion of the superior maxilla, with the subsequent characteristic ectropion of the lower lids, also affecting young children by preference

c Cold (tuberculous) abscesses of the skull, developing from small tuberculous necrosis of the skull, and generally penetrating into the cavity of the skull Most in grown people

d Tuberculous caries of the ribs

e The common form of spondylitis (Pott's hump) This affection, contrary to the traditions of the text books, should be classed with tuberculous joint inflammations, as here, after the early destruction of one or more intervertebral cartilages, the same unfavorable factors come into play as in the joints, the mobility of the separate segments against one another, the weight of the body, the progressive destruction of the inflamed parts of bone pressing against one another, and the mutual infection of the same It is to be remembered that tuberculosis of the bones in grown people almost never affects the shaft of the long bones, and therefore ostitis and periostitis developing here must generally be attributed to other causes (syphilis, chronic form of infectious osteomyelitis)

26 Even the largest abscesses, originating from tuberculous bones and joints, may be freely incised without danger, provided this be done under strictest antiseptic precautions and the after treatment be strictly antiseptic *Early opening of these abscesses is desirable* —*Langenbeck's Archiv*, Bd 33, Hft 1

FLUID EXTRACT OF PICHI IN VESICAL CATARRH —DR H S DELAMERE, of Lubec, Me, referring to the use of pichi in the treatment of catarrh of the bladder, relates the following case

"A B, æt 28, had been suffering for two years from vesical catarrh He had had gonorrhœa, but a No 21 (French) bougie passed without difficulty, causing, however, considerable vesical tenesmus When I was called to see him he was passing urine every hour during the day and four or five times during the night The urine was alkaline, ropy, ammoniacal, and the microscope revealed pus I gave the usual remedies prescribed in country practice, such as buchu, uva ursi, etc, but without benefit I then resorted to washing out the bladder by means of the double channel catheter, with the effect of relieving my patient slightly The least exposure, however, aggravated the symptoms and caused as much suffering as ever After about a year and a half of constant treatment, with no other result than to keep the disease at bay, I received a sample bottle of fluid extract of pichi, which I tried After the patient had taken it a few days he expressed himself as feeling better He was now getting up twice during the night But the sample was gone, and I was obliged to wait until I could get a fresh supply In the meantime the patient grew worse, had to get up three or four times during the night As soon as the drug arrived I commenced giving him 20 drops four times a day, which dose I increased to 30 drops In a few weeks my patient was so much better that I abandoned washing out the bladder, and to day he is at work The urine is clear, free from mucus and has no ammoniacal odor He sleeps well, and does not have to get up more than once during the night Notwithstanding he has suffered recently from a severe cold, the bladder trouble has not returned The man's general appearance is healthy, appetite good, and he seems well —*The Medical Record*, November 12, 1887

ANTIDOTES TO STRYCHNINE, RESORCINE AND PICROTOXINE —PROFESSOR ANREP[1] has proven experimentally that urethane possesses properties antagonistic to the convulsive drugs, such as strychnine, etc, and believes that urethane may be employed in cases of poisoning by these substances It is superior for these purposes to hydrate of chloral, it is less dangerous, and may be administered in large doses with perfect safety The author concludes that, in the case of man, it is necessary to administer it in doses of 4 to 6 grams as an antidote to the poisons above mentioned

E KOCH[2] states that butychloral hydrate is useless as an antidote in cases of strychnine poisoning, in picrotoxine poisoning, it fails to overcome three times the minimum fatal dose, behaving in this respect like chloral hydrate Picrotoxine may be successfully used as an antidote to the narcotic effects of butychloral hydrate and chloral hydrate According to A BOCKAL[3] paraldehyde is a powerful antidote to strychnine Ten times the fatal dose of strychnine may be safely administered to dogs that have previously received paraldehyde Strychnine is not, however, an antidote to paraldehyde —*Boston Med and Surg Journal*, November 10, 1887

THE PTYALISM OF PREGNANCY —DR JUSTUS SCHRAMM, of Dresden, describes in the *Berliner Klinische Wochenschrift* the case of a woman, æt 24, subject for a year and a half to debility, emaciation, and a feeling of pressure in the region of the stomach She was highly emaciated and very anæmic, with red, swollen gums There was also free salivation, two pints of saliva being collected in

[1] Journal de Pharmacie et de Chimie May 1887, p 505
[2] Chemisches Centralblatt 1886 p 811
[3] Ibid 1886 p 622

twenty four hours Chronic mercurialism was suspected, and iodide of potassium was accordingly prescribed, with but trifling benefit Atropine was then given, with like unsatisfactory results After nine weeks' treatment, it was found that she was at about the sixth month of pregnancy The sympathetic was galvanized The daily secretion had fallen to about 1¼ pint Pilocarpin injections were also tried, the subjective troubles were then relieved, but the secretion of saliva remained the same Lastly, Dr Schramm administered to the patient three times daily a 1 in 25 aqueous solution of bromide of potassium Henceforth there was steady improvement, the flow of saliva gradually ceased Labor was natural The progressive emaciation in this case might at first appear due to the great drain of organic and inorganic material from the system, but the solid constituents of the saliva were markedly scanty, and the loss of water could be readily compensated Dr Schramm found that, above all, ptyalin was absent from the saliva, the abnormal composition of which rendered it useless for the discharge of its important digestive functions —*British Medical Journal*, November 5, 1887

COLCHICUM IN GOUT —Whether colchicum should or should not be administered is often a question of debate DR CARTER, of Birmingham, gives his own conclusions in the current number of the *Birmingham Medical Review* He believes that this drug should be avoided in all cases attended with debility and cardiac feebleness, and that its use should be limited to early attacks of a sthenic type, and when the pulse is one of high tension From the liability of colchicum to depress the system and to interfere with renal elimination, its administration should not be continued for a longer period than is absolutely necessary for the relief of pain In order to prevent the employment of a larger quantity than is necessary for this purpose, it is desirable to give the drug in moderate doses, repeated at short intervals, rather than in a large single dose He argues that there is no evidence of the curative influence of colchicum, and thinks, with many others, that, in spite of the relief afforded, it tends to favor recurrence, and that it is safer to avoid its use altogetner if this is possible We are disposed to admit the general soundness of these views, but the evidence in favor of colchicum promoting the development of gout is not entirely satisfactory Dr Carter's observations on colchicum as a vascular depressant are rational, and he has found that such dilators of arterioles as nitrite of amyl, nitro glycerin and nitrite of sodium are scarcely inferior to colchicum in affording relief to gouty inflammations Veratria, a powerful vascular depressant, is a principal constituent in a well-known nostrum for gout Besides filling the cutaneous arterioles and swelling the skin, which actively perspires, with lowering of the general blood-pressure, colchicum diminishes the function of the sensory nerves, and may in this way tend to relieve pain, the sweating may also aid elimination, and relieve the kidneys from some of their work —*The Lancet*, October 29, 1887

CYANOSIS CAUSED BY ANTIFEBRIN —Among the points pertaining to the physiological action of antifebrin BONAI discusses this He concludes that the cyanosis which is produced in rabbits by fatal doses results from a disturbance of circulation, that in part it is due to the paralyzing action of the antifebrin upon the motor nerve endings in the muscles, and in part to a similar effect upon the respiratory centres in the medulla He does not think that it depends upon the formation of methæmoglobin, since this substance cannot he found in the blood of the rabbit In dogs similarly poisoned it can be found and in part, undoubtedly, is accountable for the cyanosis in them Upon the brain antifebrin does not seem to act, although it does have a paralyzing influence upon the sensitive elements of the spinal cord Bonai accounts for the antipyretic effects of the substance by its power of lessening the production of heat, and to this the presence of methæmoglobin contributes, since a part of the blood is no longer capable of taking up oxygen or transporting it —*Centralblatt für klin Med*, 1887, No 43

TREATMENT OF THE THIRD STAGE OF LABOR —FREUND, of Strassburg, gives his conclusions regarding this subject as follows In normal cases a judicious combination of the expectant and active method in treating the placenta and membranes is best In removing the placenta the accoucheur should wait until the first signs of spontaneous expulsion appear In cases where the placenta must be removed at once Credé's method of expulsion is the best Freund has observed, in normal cases, that the uterus rises toward the umbilicus when it expels the child He imitates, with one or both hands, this action in securing the expulsion of the placenta by gently pushing the uterus upward, and at the same time compressing it —*Deutsche medicinische Wochenschrift*, October 27, 1887

INFLUENCE OF POTASSIUM IODIDE UPON THE ELIMINATION OF MERCURY —According to DR SOUCHOW the elimination of mercury commences later, and the quantity eliminated is relatively less in those cases in which the patient takes potassium iodide in conjunction with the mercurial preparation If the iodide is administered during or after the mercurial course, the quantity of mercury eliminated daily is lessened The iodide, therefore, appears to prevent the elimination of mercury, instead of hastening it, as has been believed by some, and would seem to be useless in cases of mercurial poisoning —*Boston Med and Surg Journal*, November 10, 1887

SYNCOPE FROM SYRINGING THE EAR —MR J MIDDLEMASS HUNT reports the case of a boy, æt 3 years, whom he found in profound coma, with slow, irregular respiration, rapid pulse, and dilated pupils, a condition which came on immediately after his ear was syringed for a purulent discharge Mustard was applied to the nape of the neck and consciousness returned in a few minutes The membrana tympani was extensively destroyed, but there were no signs of caries Roosa records a similar case in the *Archives of Ophthalmology*, vol ix, p 19 —*Lancet* Oct 15, 1887

INJURIES TO THE FŒTUS DURING LABOR

The exhaustive article on this subject, by PROFESSOR PARVIN, which is published in this issue of THE JOURNAL, will, we are sure, be read and studied with the greatest interest And while it would be superfluous to go over, in this place, the points he has so ably presented, it may be interesting to notice some points brought out in the discussion following the reading of his paper, a discussion that must be regarded as a timely opening up of a very important and interesting subject, and participated in by Drs W T Lusk, W Goodell, Wharton Sinkler, C B Nancrede, H C Wood, and others

In regard to fractures of the skull occurring in spontaneous deliveries, DR LUSK mentioned a case reported by Veit, in which the patient received large doses of ergot The child was born with the right parietal bone separated from its fellow, from the occipital, and to a great extent from the frontal bone, the parietal itself being fractured in two places Dr Lusk raises the question whether the cases of spontaneous fracture reported many years ago were due to the absence of "this certainly most unreliable drug"—ergot He seems inclined to think that in some cases of depression of the skull it might be good practice to trephine, and elevate the depressed bone With regard to delivery of an after coming head retained by tonic retraction of the uterus, it must be remembered that great traction force—and certainly less than 160 pounds in most cases—will almost surely tear the cervical tissues If the head be retained at the brim of the pelvis, it is almost a matter of certainty, he thinks, that the child will be stillborn when the necessity for that amount of force exists, "it is a question whether we should ever use much force in pulling on the child, whether, indeed, the head cannot be better shoved through the pelvis by supra pubic pressure, in the manner described by Dr Goodell and Dr Taylor" But Dr Goodell, in discussing the paper, said With regard to head last labors, I have tried to deliver the breech by the use of the forceps on the buttocks, and have succeeded with them, but they are liable to slip off I therefore always bring a leg down in breech cases, and then I have command of the situation The force of traction which the neck will bear is uncertain, and doubtless varies greatly, but I believe that the man who, in trying to save the child, breaks the most necks, saves the most children, and I respect him accordingly Such labors are always very dangerous to the child, the percentage of deaths is a very large one I look on a child in breech presentation as a child drowning, to which help must be sped—help at all hazards It is emphatically a case of "neck or nothing," and we must not sacrifice the life of the child to any sentimental considerations about breaking its neck

A point emphasized by Dr Lusk is that when the blades of the forceps cannot be applied to the sides of the head, they should be applied in the oblique diameter, otherwise, the blades may press directly on the forehead and occiput, and the pressure will ultimately affect the medulla, destroy the respiratory sense, and kill the child It is especially in the flattened pelvis that this may occur, or that the pressure of the forceps may dislocate the occipital bone In labor cases in which the arms become extended above the head—a thing that should not occur in a well conducted labor—he thinks that the accoucheur is justified in breaking the arm to effect delivery It is not always possible to follow the directions of obstetricians, to draw on the elbow and push the arm over the face, in time to extract the child alive And in breech cases, in which the arm is bent around the neck of the child, it is almost impossible to extract the arm without fracture "Then why not fracture the arm?" The physician is not responsible if the arm be broken in his efforts to release the member, "but he is responsible for the displacement of the arm behind the head If he leaves the body alone and does not twist the trunk, the arm will not remain extended The child does not spontaneously flex its arm and place the forearm beneath the occiput" In cases of breech presentation, with both extremities reflected upwards, and when the breech has reached the floor of the pelvis, Dr Lusk still thinks that the application of the forceps is

easier than would be supposed, and that their use is less dangerous than that of the fingers or the blunt hook If the breech be brought down to the perineum and then allowed to recede, and this be continued till physiological softening of the pelvic floor and perineum takes place, only a moderate degree of force is required

Dr Wharton Sinkler's experience is that a very large proportion of the cases of paralysis met with in infants are due to instrumental or prolonged and difficult labors The most frequent form that we meet with is facial paralysis, either unilateral or bilateral This generally results from the pressure of the forceps upon the facial nerve or upon the mastoid process Facial paralysis may, however, result simply from the impaction of the child's head in the pelvis without the use of forceps Hemiplegias are often met with in the newly born as a result of the use of the forceps In regard to injuries to the sterno-cleido-mastoid muscle, he has seen cases in which the child has lost power in all the muscles of the neck so that it was unable to support the head Some of the cases have been delivered by the breech and considerable traction made Some have followed delivery by forceps, perhaps from pressure on the spinal accessory nerve, or perhaps from extravasation of blood In the case of paralysis following difficult or instrumental labors, the lesion is often an extravasation of blood over the motor convolutions, a meningeal hæmorrhage If the amount of the extravasation be great, the prognosis is, of course, bad, but in some of the cases, especially when there is monoplegia, when there is paralysis of one arm alone, the child entirely recovers the use of the limb, and in facial paralysis recovery, as a rule, occurs in a few days, but the condition may persist during life Dr H C Wood explained that we do not see hemiplegias and paraplegias due to injury during labor, in children of 5 or 6 years, simply because children so injured never live that long What we do see are the cases of spastic paralysis Spastic paralysis is the secondary effect of an early destructive lesion, the immediate evidences of which may have been entirely overlooked "In all such cases presenting at my clinic I inquire as to the history of the labor, and invariably find that it has been unusually severe or instrumental The brain at birth is so soft, so liable to injury, that while I would not have the obstetrician entirely discard the use of the forceps, I think he should never take them in his hand without bearing in mind the possibility that they will do serious permanent injury to the nerve centres of the child"

Dr Nancrede believes the treatment of the injuries of the soft parts is too often left to the nurse, who either does nothing, or does that which ought not to be done It has been recently shown that even the slightest injury of the scalp may end in periostitis, inflammation of the sinuses, meningitis, encephalitis, and often pyæmia The prompt carrying out of antiseptic precautions greatly reduces the mortality from such injuries Although in these cases certain forms of antiseptic dressing may be impossible, the principle of antisepsis is easily carried out in many ways The Lister dressing, or the application of any irritant or poisonous substance, is out of the question But we may use boric acid freely, and it has the special advantage of being a dry dressing "I would call attention to the fact that simple fracture of the skull is in itself of no consequence The injuries to be feared are those done at the same time to the adjacent tissues by the force which produces the fracture If I should ever see a case in which I was convinced that existing paralysis was due to depression, I might trephine The recently published statistics that seem to indicate that trephining under antiseptic precautions is entirely without danger, are not to be relied on, and while I am a thorough believer in antisepsis, I must call attention to the fact that as inflammation of the membranes or brain may occur from injury, without any break of the cutaneous surface whatever, you certainly may have the same after, and because of trephining, despite antisepsis Trephining cannot remove many of the conditions referred to by Dr Sinkler, which are the real sources of danger, such as effusion of blood upon the surface of the brain or in the arachnoid Fractures producing epileptic seizures, etc, later in life, are rough fractures where projecting spiculæ or rough edges impinge on the brain or membranes, and such fractures—except, perhaps, *very rarely*, projecting rough edges—cannot occur in the infant skull, which is *devoid of* an internal table, from the shattering of which, in fractures in adults, secondary nerve trouble results"

THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION

A meeting for the permanent organization of this Association was held in Birmingham, Alabama, on the 12th of October, 1887, pursuant to a call by the Alabama Surgical and Gynæcological Association, which had been prompted by requests from many prominent physicians in the Southern States asking the Alabama Association to so extend

its membership as to include members from all the Southern States The meeting was organized by the election of Dr H N Rosser, temporary Chairman, and Dr W E B Davis, Secretary A well considered Constitution and By-Laws were adopted The second, third, and fourth Articles of the Constitution are as follows

"ART II The object of this Association shall be to organize the profession of the South in the most efficient manner possible for the advancement of the sciences of surgery and gynecology

"ART III This Association shall adopt and conform to the Code of Ethics of the American Medical Association

"ART IV Any reputable physician, who practices surgery or gynecology, and who is vouched for by two members of the Association, and recommended by the Judicial Council, shall be eligible to membership in this body "

The following officers were elected for the ensuing year President, Dr W D Haggard, of Nashville, Tenn , Vice-Presidents, Drs R D Webb and J W Sears, of Birmingham, Ala., Secretary, Dr W E B Davis, and Treasurer, Dr H P Cochrane, both of Birmingham, Ala The Constitution provides for annual meetings, to be held on the second Tuesday in September at such places as may be designated from year to year The next annual meeting is to be held in Birmingham, Ala , commencing the second Tuesday in September, 1888 Dr W F Hyer, of Holly Springs, was elected Orator If the object of this new movement as declared in the second article of the Constitution shall be faithfully adhered to, as it doubtless will be, it will contribute much to advance both the social and scientific interests of the profession in the Southern part of our country The association of surgery and gynecology in one Association can hardly be considered inappropriate, since the gynecology of to day takes cognizance of little else than surgical procedures of some kind

NEW YORK HARBOR AND QUARANTINE FREE FROM CHOLERA

Such was the announcement when a few days since the last of the passengers of the Alesia, who had been detained several weeks in quarantine, were landed at Castle Garden in good sanitary condition As the disease is rapidly diminishing in Italy and Mediterranean ports on the approach of the cold season, there is less probability of having more cases brought to our ports on shipboard during the next three or four months, but the danger of importing infected cloth ing or goods either directly or indirectly from places where the disease has been prevailing is not materially lessened And the fact that such baggage may belong to passengers in good health, adds to the danger that it may escape detection by the health officers and be permitted to be carried to any part of the country From the report of the Committee appointed by the Philadelphia College of Physicians, and from other sources, we think the system of inspection, detention and isolation of the sick at New York is more nearly complete, and affords a greater degree of protection from the introduction of contagious and infectious diseases than is afforded by the quarantine arrangements of any of our other important seaports In one important respect, however, the system of New York, or rather the accomodations for rendering it most efficient, is defective It is the failure to provide on the Island for detention of passengers from infected ships, a sufficient number of entirely separate cottages or barracks to permit the passengers to be accommodated in small groups The detention of passengers who are well, after they and their baggage have been subjected to thorough cleanliness and disinfection, can be justified only on the supposition that they may have the infection already in their blood undergoing the incubative stage, and hence they should be held until the known period of incubation has passed But if all the passengers are detained in one company, and only one case of the disease develops among them at the end of the period of incubation, whether it be seven, nine or fourteen days, the whole company are exposed again and must be detained during another period of incubation, and so on While if the passengers had been from the first kept in small isolated groups, all the groups except the one in which the single case developed, could have been safely discharged at the end of the first period of incubation Hence the practice of keeping all the passengers from an infected ship quarantined in one company, whether they number fifty or five hundred and thereby exposed anew to every new case that develops among them, is both unneccessarily expensive and unjust

THE TENTH INTERNATIONAL MEDICAL CONGRESS IN BERLIN, 1890

Soon after the adjournment of the recent International Medical Congress in Washington, the action of that body in recommending Berlin as the place, and 1890 as the time, for holding the next International Medical Congress, was officially communicated

to Professors Virchow, von Bergmann and Waldeyer, of that city Through Dr A Martin, of Berlin, the reception of the communication has been acknowledged, and assurances given that they cordially accept the proposition to hold the Tenth International Medical Congress as proposed The letter of Dr Martin, addressed to Secretary General Hamilton, gives assurance that so soon as the necessary preliminary conferences can be held, an official communication will be sent This we shall take much pleasure in publishing as soon as it is received, and the columns of THE JOURNAL will be used freely for the promotion of the interests and success of the Congress to be held in Berlin, 1890

INFLUENCE OF OCCUPATIONS ON MORTALITY —The English Registrar-General has recently given the results of a comparison of the death rate in classes following different occupations in England, that are worthy of serious consideration Assuming the average death rate for the whole population to be 1,000, the comparison shows the lowest death rate to be with ministers of religion, 556, gardeners and nurserymen, 599, and farmers and graziers, 631 On the contrary, the highest death rate was with those directly connected with the liquor traffic and hotel service, 2,205, the general laborers in London, 2,020, the innkeepers, 1,521, and the brewers, 1,361

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, May 25, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

DR J FORD THOMPSON showed the specimen and gave the history of a case of

TAIT'S OPERATION

The patient was under the care of Dr Freidrich and was seen by him in Nov, 1886 She was the mother of 9 children and had had besides 3 abortions She has suffered intensely since her last abortion two years ago The pain was mostly in the left side She had been operated upon for a lacerated cervix some time ago by Dr J T Johnson She was having convulsions of an hysterical nature whether from the ovarian trouble or not it was difficult to determine for the history of their occurrence extended back to before her marriage The convulsions would occur while she was being examined Several consultations were held and it was agreed by all who saw her that a removal of the uterine appendages was the only chance of curing her Her husband and herself being perfectly willing, the abdomen was opened Dec 6, 1886 The uterus was found to be retroverted, the left Fallopian tube was enlarged, which together with the retroverted uterus prevented his reaching the ovary on that side After a consultation with those present it was decided not to proceed further, so the wound was closed The right ovary could have been removed with ease but here frained from doing this because it would not make a complete operation and there was apparently nothing the matter with that ovary The woman recovered from the operation all right, and remained well for a month when the symptoms returned with renewed violence

The husband and patient ardently urged another operation, and, Dr Taber Johnson having been called in consultation, it was considered justifiable The second operation was undertaken with reluctance as the difficulties were known in advance The incision was made in the line of the first one, and he was, on getting through the peritoneum, embarrassed by what seemed to be intestine adherent to the wound It proved to be omentum and was easily got rid of The retroverted uterus was tipped forward by one of the assistants and the left-ovary was at last reached It proved not to be enlarged, as might have been expected, but very firmly adherent Starting, therefore, at the uterine end of the tube he passed two ligatures around it and cut between them A little more of the tube was then taken up in the same way He now turned to the right ovary which was found to be enlarged and somewhat adherent The adhesions were broken down and the ovary and tube removed He now went back to the left ovary and after much difficulty succeeded in shelling it out of its bed and removing it There was but little hæmorrhage in spite of the lacerations on the left side The wound was closed by silkworm gut and quickly healed by first intention

About a week after the operation he detected fluctuation on the right side and there was intense pain over this region A few days after this there was meteorism and slight tumor in the right inguinal region He cut down upon the tumor and evacuated a large quantity of pus from a pelvic abscess He washed out the cavity and inserted a drainage tube, and the patient is now well

The left ovary might possibly have been removed as usual but taking it out in sections seemed to have made no difference in the result The case was an extremely bad one from the outset but she has now recovered from the operation and he hopes to have cured her

DR JOS TABER JOHNSON reported

FOUR CASES OF REMOVAL OF UTERINE APPENDAGES

Case 1 —Miss B, æt 26, began to complain of pain in left side and abdomen in the Spring of 1874 Had also a hacking cough which greatly aggravated the pain She was treated for asthma, rheumatism, neuralgia and diabetes, without benefit In 1880 consulted another physician who diagnosed a retroversion of the uterus aggravated by long inattention, but curable This history is given from a written

statement made to me by the patient and I continue, using her own words "I was treated for this retroversion and cough for three years, and at the end of this period not being satisfied with my progress, consulted another physician The most distressing feature of my condition was the neuralgic attacks, as they were called, but are now said by Dr Johnson to be recurrent attacks of pelvic peritonitis Beginning sometimes with nausea, oftener with a beating pain at the base of the spine which gradually increased until it came in surges, enveloping the entire abdomen and stomach, lasting generally an hour and in effect several days These attacks invariably followed any variation in the simple life I was at that time obliged to lead Dr S abandoned the pessary and in addition to local treatment, attempted to build up the system by tonics, etc This plan entirely failed, and in the Summer of 1883 (being North as usual), occurred the most violent of these attacks above alluded to, which was a four weeks' siege During 1883 and 1884 I had a number, more or less violent In the winter of 1884, while in Boston, I consulted Dr B, and under his advice commenced the use of hot soft baths and douches to remove an adhesion which he said existed After sixteen months trial of these baths and iodine and the intermittent use of the pessary, I returned to Washington very little benefited Under the treatment of Dr Jos Taber Johnson I was enabled to do without the pessary for some time, but still suffered when I walked or took any exercise from my chronic ovarian inflammation as he called it By his advice electricity was tried about twice a week, administered by Dr Cuthbert, for a year, but no permanent relief was obtained Dr Busey was called in consultation and after listening to my history said that as about every thing which he would suggest had been already faithfully tried, he had only two suggestions to make, one that I remain in bed for a year and the other was that the ovaries be removed As I had been practically at rest for the past three years, that course did not promise much Dr J had already talked of the operation, and after thinking the matter over and talking with my family and friends about it, and after having a full explanation of its effects and possibilities I concluded to have it done"

Miss B entered the hospital March 6, 1887, and her ovaries and tubes were removed on the following day, in the presence of Drs Cutts, Cuthbert, S S Adams and the house physician Not much trouble was experienced in the operation and the patient made a rapid and perfect recovery She has had no menses or pain in the abdomen since and is perfectly satisfied and happy over the results She still has her asthma, and when she walks or stands too long has symptoms produced by her retroverted uterus and pressure on the rectum, but these are gradually disappearing I am doing nothing for her, expecting the atrophy which accompanies the change of life to finally relieve her uterine symptoms In answer to a note inquiring her present condition for the purpose of adding to the history of her case, I received, yesterday, the following reply

"Monday, May 23, 1887 My dear Doctor I am more and more thankful that I had the operation done, and will not have to drag out my days in endless pain and misery. I have been entirely free from the old pain and as soon as I can regain my strength I expect to be unusually strong and well This I am slowly, but surely, doing Sincerely, etc Lilla B"

Case 2—Mrs B, æt —, married, children With in the last — years has been greatly troubled by profuse menstruation, which at times amounted to fearful hæmorrhages I was requested to see her by her physician, Dr C W Franzoni He had already discovered a uterine fibroid which he thought was the cause of the loss of blood Upon several occasions she was greatly reduced by the flow, and hardly recovered from its effects before another one came Twice it was feared that she might bleed to death before the hæmorrhage could be arrested After a careful examination and deliberate consultation it was agreed that Tait's operation for the relief of bleeding uterine myomata offered the best prospect, and it was therefore recommended after a course of treatment with ergot The husband and wife readily agreed to take the risks, which were fully explained to them Mrs B entered a private room at Providence Hospital on the 13th of February last, and the operation was performed two days later, in the presence of Drs Franzoni, Cutts, Cuthbert, Crook and the house physician She made a good recovery and has had no loss of blood since the operation She is now well and hearty, and attends to household matters as well as she did before the growth of the tumor

Case 3—Mrs H, from Georgia, æt 30, married for fifteen years, no children, has been a sufferer from pain and hæmorrhages for the past seven years She was for some time under the care of Dr Robert Battey, of Rome, Ga, and became an inmate of his Infirmary for the purpose of having her ovaries removed to cure the fibroid enlargement of her uterus, which was diagnosed to be the cause of the hæmorrhages Just before the time fixed for the operation Dr Battey was unfortunately taken sick, and as the date of his recovery was doubtful, and she had gotten her courage up to the point of an immediate operation, she determined to come North and have it done before her next period should set in and exhaust her again by such a dreadful loss of blood as occurred every month Indeed, she and her two sisters, who came with her, feared she would not survive another period

Upon examination I found a fibroid tumor reaching nearly to the umbilicus It fortunately did not press upon the rectum, though it greatly interfered with the bladder She was very nervous and especially feared meeting with strangers She was entirely satisfied with Dr Battey's diagnosis, and as I perfectly agreed with him in the propriety and necessity of removal of the uterine appendages as a means of cure, she and her sisters declined any further consultation As soon, therefore, as she was rested from her journey, and five days before she expected her next period, I removed her ovaries and tubes in the presence and with the assistance of Drs Cutts, Cuthbert and the house physician, Dr Luce

A large vascular fibroid growth lay directly under the abdominal incision It was turned somewhat sidewise, bringing the left ovary and tube very easily within reach It was drawn out of the wound, and with the Fallopian tube removed without any difficulty The ovary was enlarged to double its natural size and in one extremity was a hæmatoma which ruptured in my fingers The other ovary was far down under the tumor, and it was with the greatest difficulty brought up sufficiently to enable us to get a ligature under it I feared to draw too strongly on the very vascular looking tumor, having in mind several experiences of Dr Keith where, under similar circumstances, he had accidentally torn the covering of the tumor and set up hæmorrhage requiring the performance of hysterectomy to control it I transfixed and ligated under the ovary, but could not remove the entire organ without endangering my ligatures The cautery was, however, very thoroughly applied to the stump, thus destroying, it was thought, any of the ovarian stroma left behind

The patient has made a good recovery It is now three weeks since the operation, and no menstrual flow has made its appearance, though one was due and expected five days after the removal of the appendages

In the last two cases the ovaries and tubes were removed solely for the purpose of arresting the growth of uterine myomata and their accompanying hæmorrhages, and without the slightest purpose or thought that they were themselves diseased Experience has amply demonstrated the value of this mode of treatment of small uterine myomata When these tumors are very large, say from 15 to 50 lbs, ergot, electricity or hysterectomy, in the order mentioned, offer better prospects of a cure

Case 4 — Miss B, æt 23, single, began to menstruate in 1879, when she was 13½ years old Has from the first suffered with much pain and has always been irregular Pain in back, hips, limbs, head and neck and nausea which for years has prevented her from taking sufficient food Pain at first in left ovary, but of late years worse in right, especially during her periods, formerly attended with slight convulsions Has never been able to take violent exercise, such as running, dancing, jumping, etc, without producing severe pain in her side, sometimes the left, at others the right, with headache Of late years could not attend church, go in company, or stand any excitement, so that life gradually became a burden with scarcely any pleasure in it Had typhoid fever in 1882, and two and one half years elapsed before her periods returned again During this time she frequently had convulsions, just about the time for the regular flow, but with no sign of a flow She says in her written statement to me "The convulsions generally lasted two or three hours, and I was generally very sick for two or three days afterwards Since the return of the menses they have been more painful than ever For the past year and a half I have not been able to walk three squares, cannot sweep, dust, or go up and down stairs or lift any ordinary weight, or stand on my feet for any length of time, without it producing pain in my back and in the lower part of the abdomen, generally worse on the right side, and intense bearing-down feelings Any exertion of the arms produces severe pains in the back of the head and neck, this pain is much worse during the monthly periods I am so nervous all the time that any excitement, fright, sudden joy, or any sudden noise will make me start, and sometimes produce a nervous chill lasting fifteen or twenty minutes The monthly flow is generally attended by intense itching and burning and great soreness of the parts I have used the hot water injections for years, but I found it was not benefiting me any, so I gave it up Have been treated for falling of the womb, used cotton supports and pessaries, but they did me more hurt than good Have had a dry hacking cough and palpitation of the heart"

Dr Little brought this lady to me about four months ago After hearing her history of pain and suffering for some years, I suggested the removal of the uterine appendages as the only rational mode of treatment This was opposed, and I have treated her with various applications, iodine blisters, tonics, feeding and electricity I did her no good for three months, and then declined to treat her further, repeating my first advice I saw nothing else to do, but advised her to seek other advice and return to me in six months, if no better In about one month she returned Both she and her family requested to have the operation performed Its risks and effects were fully explained She took a private room at Providence Hospital, and I removed her appendages last Monday at 10 A M, in the presence of Drs Cutts, Cuthbert, Little and Luce

The uterus was a good specimen of what is called the infantile uterus The ovaries were adherent, one was difficult to remove on this account, and was enlarged and contained cysts They both appear to be in a state of chronic inflammation The patient is doing fairly well so far Her pulse has been too rapid since the operation, but she shows no evidence yet of peritonitis I expect she will recover and be cured

DR JOHNSON also reported a case of

CÆSAREAN SECTION, DEATH ON TENTH DAY

I was summoned by Dr J W Bayne early on the morning of April 5th to perform Cæsarean section upon a colored woman who had already been more than two days in labor I made the necessary preparation and went to the residence on New Jersey avenue, about four squares southeast of the Capitol We found her in a little hut nearly if not quite fifteen feet below the level of the street The place was devoid of anything which might properly be called furniture, but was thoroughly filled with smoke from a rickety old stove, and bad smells There were from six to ten colored women, and a few men and boys, standing about, and with the four doctors who had been in attendance during the night, and myself, we made a curious and anxious audience of a dark and tragic scene

The following is a history of the case Mrs J, colored, age uncertain, but said by her mother to have been born ten years "fo' de wah," and the

mother of six children, had been unusually weak troubled with a cough during the last three months of her pregnancy Was taken in labor two days before and sent for Dr Chew, after pains had been going on for some time He found the head of the child in the left iliac fossa, but it had not and could not be made to properly engage After much waiting forceps were applied, they repeatedly slipped off, and Dr Chew then called to his assistance Drs Mallen, Dunn and Bayne During the night before I saw the patient she had been at one time under the influence of ether four hours, while prolonged and repeated efforts were made with the forceps Version also failed to dislodge the head, although one foot was drawn down and out of the vulva The head could not be pushed up by any of the gentlemen Dr Bayne finally performed craniotomy in the hope of so diminishing the size as to enable him to extract it Effort at delivery with the crotchet and blunt hook entirely failed When I saw her and learned that she was the mother of six children, and that craniotomy had already been performed upon this child, I expressed the belief that she could and ought to be delivered without Cæsarean section I was invited to try, and the patient was etherized and I did try, but the impaction was so great and the contractions of the uterus so continuous and powerful that I accomplished absolutely nothing All present were anxious that the child be immediately delivered, including the mother and husband, and I reluctantly consented to proceed with the operation

The surroundings could not have been worse, unless it had been in the night We made the best preparation we could An operating table was improvised by taking a door off its hinges and placing it across the backs of two chairs I made an antiseptic solution by using some of Wyeth's tablets of the bichloride, and with it washed the patient's abdomen I placed my instruments in a bowl of hot water The patient was as well protected with blankets as we could provide The urine was drawn off by Dr Mallan, and with Drs Chew, Bayne, Mallan and Dunn to assist, I began the incision just below the navel, and cut rapidly down upon the uterus, to within about two inches of the os pubis There was scarcely any hæmorrhage Dr Bayne skilfully compressed the walls of the abdomen against the uterus, thus preventing any escape of intestine, and at the same time preventing any fluids from the uterus entering the abdomen, and steadying the organ itself Expecting much loss of blood as I cut into the uterus, I hastened this part of the operation, and as soon as the child was visible extracted it and the placenta without any difficulty Dr Bayne at once compressed the fundus, completely preventing hæmorrhage from the placenta site I doubt if two ounces of blood were lost in the entire operation

The uterine cavity was sponged out with the bichloride solution, or rather the water was squeezed out of the sponge into it The muscular structure was brought together with eight interrupted carbolized silk sutures, thoroughly coaptating the cut surfaces Effort was made not to include the mucous coat, and as the post mortem shows, sufficient hold does not appear to have been secured by the last three stitches

After cleaning out the abdominal cavity, the incision in the walls was united by about fifteen sutures, and the wound was dressed with iodoform gauze, a firm compress and flannel bandage The operation was completed in about fifty minutes The patient was made as clean and comfortable as circumstances would permit She was placed in a large bed in which she had been wallowing about for the two previous days of her labor, and which had done duty for a large family for a long time, clean sheets and pads were loaned by the neighbors, and the bed filled with hot bottles, bricks and flat irons, to restore and retain warmth to her body Her pulse could not be counted the first twenty four hours after the operation, and she had a number of hypodermics of whiskey

I should have mentioned that when the abdomen was opened, we could all plainly see where the uterus had been bruised, and had turned very dark—almost black—where the head had been impacted so long, and the parts bruised and injured by the repeated efforts to press and push it out She rallied very well, and seemed free from pain, and after the first thirty six hours took a large quantity of liquid food Her pulse continued between 130 and 120 for several days, but her temperature remained at about 101° She seemed at one time to have a fair prospect of recovery, but the circumstances were all against her She had no nurse, was on a bed reeking with foul smells until Dr Chew and I bought and fitted up a cot upon which we lifted her We changed her clothing, washed and dressed her daily, begged linen and under clothing for her from our friends, washed out her vagina and uterus frequently I saw her twice daily, and Dr Chew six times daily, the last visit generally about midnight She could not have had more medical attention if she had been a millionaire Upon the evening of the 9th day her pulse began to fail, though her temperature was only 101° She lost her desire for food, and died at 10 A M on the 10th day after the operation

I asked Dr Lamb to make the post mortem She seems to have died from the effects of an abscess found below my incision in the uterus, which was probably the result of the bruising of the uterus in the vain effort to push the head out of the left iliac fossa where it was so long impacted, and also by the general nastiness of her environment

It may surprise members of the Society that the operation was necessary at all I was at first surprised myself, and declined to perform it until after I had failed to relieve the impaction with the woman thoroughly etherized I think if any objector had been with us, he would have agreed finally with us It might perhaps have given the woman a better chance if the bruised uterus had been removed altogether, according to the Porro method, but the gentlemen present all agreed upon the Caesarean section, and it was done Great care was taken to bring the serous surfaces into perfect apposition, and the post mortem shows it to be thoroughly united

Dr Parish, in the last number of the *American Journal of Obstetrics*, gives an account of a Porro-Muller operation, performed on account of impacted shoulder presentation There are some points of resemblance between his case and the one just narrated His patient had been several days in labor Several skilled obstetricians had failed after prolonged and repeated efforts to produce podalic version, the patient having been six or seven hours during the last day of her labor under ether There was an unrelieved impaction The uterus was so firmly compressing the body of the child that it was found after many trials by four good obstetricians to be practically impossible to turn and deliver it In his case, as in mine, Cæsarean section was agreed upon, all knowing the child to be dead, and it was deliberately chosen as the mode of delivery instead of embryotomy Dr Parish subsequently determined to remove the uterus on account of the damage which that organ had sustained His patient died in less than two days, mine lived ten days, and died finally, as I believe, of an abscess at the point where the greatest bruising had occurred I have an idea if the Porro operation had been performed, thus amputating the uterus below the injured point, and she could have been so circumstanced as to have had proper nursing and hygienic surroundings, she would have recovered

Dr R P Harris, in the discussion of Dr Parish's paper, remarked that "the Cæsarean operation has been performed in the United States in cases of impaction of the fœtus in a transverse position twelve times" In eleven cases the fœtus was dead, in two only of the twelve was the pelvis deformed, nine, or 75 per cent recovered, of the three lost one was ninety-six hours in labor, three days in charge of a midwife, another was twenty six hours under a midwife who had given ergot and ruptured the membranes, and the third had been long in labor, time not stated In these cases of impaction of the fœtus in transverse positions, we do not have presented to us the indication for the early Cæsarean section so eloquently pleaded for by Dr Harris, which is present in cases of pelvic deformity In these latter cases a knowledge of pelvimetry will demonstrate the impossibility of extracting even a craniotomized child through the natural passages, but in the former cases physicians are actuated to delay by the hope of being able to break up the impaction, and to finally deliver the child *per vias naturales*

It is rare that the uterine contractions become so constant and tetanic as not to relax and yield under the influence of prolonged anæsthesia

It becomes a nice point to decide, especially in women who have previously given birth to live children, in any given case of impaction when efforts with the forceps or by version should be suspended, and the Cæsarean section or the Porro operation proceeded with The 75 per cent of recoveries in cases of the Cæsarean section in the United States, for the relief of impaction in the transverse position, reported by Dr Harris, gives no great encouragement to study these cases more strictly, but it seems to me there will always remain great doubt when to suspend efforts at delivery through the natural passages and to perform the Cæsarean section or some of its alternatives

Mrs J , colored, died May 4, 1887 Necroscopy by Dr S S Lamb, abdomen only examined Track of incision in abdominal wall partially healed A delicate pseudo membranous layer united front of uterus to abdominal wall Some hyperæmia of peritoneum Pus in utero vesical pouch Lower three inches of anterior wall of uterus contained eight interrupted sutures (silk), around some of these suppuration was going on The uterine incision had healed except where the lower sutures had failed to include the entire thickness of wall Internally the uterine surface was red, green and blue, and soft, towards the vaginal end were two pus pockets and uterine surface was gangrenous Vagina showed sloughing ulcers

DR BUSEY asked Dr Johnson why he could not turn, in the case upon which he did Cæsarean section, and also if any ergot had been given?

DR JOHNSON replied that he attempted to turn, but could only get his hand up a little way when it came to a full stop The case had been in the hands of a midwife for two days before she was seen by a doctor, and he does not know whether ergot had been given or not

DR BUSEY remarked that in one of the histories read by Dr Johnson and written by the patient, he is quoted by her as having advised her "either to remain in bed a year or submit to the operation" His recollection of the advice he gave differs from this statement He does not know why he should have advised her to have remained in bed a year, as he cannot conceive that it would do her a bit of good He agreed with Dr Johnson as to the advisability of the operation

DR JOHNSON thought that the patient had grounds for the belief in this way, in the course of the conversation, as he recollects it, Dr Busey told her that as everything had been done for her except lying in bed for a year, she might get some good from this treatment, but that other disorders would likely be engendered which would be nearly as bad as the present trouble

DR T C SMITH said that he did not criticise Dr Johnson's treatment by Cæsarean section, but he wanted to call attention to the fact, that this is the fourth operation of the kind done in this city, and that the mortality was 100 per cent The point is that there are cases which ultimately require Cæsarean section, but which do not appear to at first As in this case the woman had the best of treatment without success, and then Cæsarean section had to be resorted to The operation is unfortunately looked upon as a *dernier ressort* From what we know of this case now, it seems as if the woman would have had a better chance of recovery if the operation had been done earlier, but no doctor here would have done it then The bruising of the uterus which is present might have been avoided by an earlier operation As it was the woman would probably have died anyway

DR J FORD THOMPSON said that he wanted to say a few words in regard to the technique of Dr Johnson's operation If he operated as he described it the Saenger method was not followed exactly For instance, no temporary ligature around the neck of the uterus was used This is a very important step, as without it hæmorrhage on removing the placenta is very probable, while with it, the subsequent steps can be done leisurely The serous surface under the sutures, also looks as if it was healed, but it is not united by Saenger's method of suturing It is the safest, first to use a line of buried stitches, and then put in the interrupted Czerny Lembert suture—which is the method now being used

DR JOHNSON remarked that Dr Thompson's criticisms were pertinent, and in the line of perfecting the operation There were two reasons why he did not apply the ligature One was, that he did not have one, and the other was, that the child having been dead for so long he did not expect much placental circulation There being some doubt as to the patient's getting off the table alive, the wound in the uterus was closed as quickly as possible If we could take the steps as deliberately as did Dr Tusk recently, there might be some chance of success (See THE JOURNAL, May 21, 1887) He agreed perfectly with Dr Thompson in the propriety of operating upon the case he has just reported, and he thought his prompt evacuation of the pelvic abscess probably saved her life The adhesions found were, he thought, a perfect explanation of her sufferings

Stated Meeting, September 23, 1887

THE PRESIDENT, DR JOSEPH TABER JOHNSON, IN THE CHAIR

DR T C SMITH presented and read the history of a case of

HYDATIDIFORM MOLE

(See page 686)

DR KING Such a valuable paper should not be passed without some comment In fact, so little is known of such growths that there is not much to say, and Dr Smith has covered the whole ground in his paper The history is the usual one of suspected abortion He had a case some years ago in which he diagnosticated hydatidiform pregnancy, and wished to empty the uterus, but the patient declined the operation, stating that Dr J H Thompson (Columbia Hospital) had wanted to do this three months before, but she would not allow it After three or four months she was attended by the late Dr Drinkard for the same trouble, which was at first considered to be an abortion

THE PRESIDENT said that there were several interesting points in the paper Recurrence is usual in such cases The fleshy moles deserve consideration The liability of the woman's character being affected should guard us in the diagnosis

DR KING Moles are of two kinds, true and false, the first occur with pregnancy, but the second do not If the mass be due to pregnancy, the chorial villi can be detected by the microscope after washing away coagulated blood clots in a basin of water False moles, having no connection with pregnancy, might be due to semi organized blood clots, polypoid and fibrous growths, and the desquamated membrane of membranous dysmenorrhœa This last could be diagnosticated by the membranous sac preventing three openings, those of the two Fallopian tubes and the internal os uteri The main point of differential diagnosis is the detection of chorial villi in true moles

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

DR F I KNIGHT, CHAIRMAN

ALBERT N BLODGETT, M D, SECRETARY

Regular Meeting, Wednesday, October 12, 1887

DR W EVERETT SMITH read a paper on

A CASE OF POISONING FROM ARSENICAL WALL PAPER

About the middle of September, 1886, my patient, Mrs S, changed her residence from the country to the city She very soon discovered that some ferns in her parlors were withering, but not from neglect or improper care, since although ultimately dying, they revived for a brief season upon being removed to another part of the house In the early part of November, she suffered from an attack of nausea and a dizziness so intense, especially when she attempted to stoop, that for several days she was obliged to keep the bed These symptoms persisted in their intensity about a fortnight, and were followed by a sharp attack of facial neuralgia which lasted about a week In the latter part of December, the dizziness re appeared, but in a far milder form than it had been the month before At about the same time she began to complain of extreme lassitude and a loss of pleasure in pursuits that formerly gave enjoyment The quiet of her own room was the one thing that she eagerly sought

Although she suffered from a continual slight nausea, her appetite was unusually good, there was, as she expressed it, an almost constant "gnawing in the stomach" After the eating of food the nausea would increase, and she would complain of a feeling of heaviness and uneasiness throughout the bowels, especially in the umbilical region Her increase of adipose tissue began to be distressing to her Although she had always before drank very little water, she now was thirsty all the time The menstrual functions continued to be regular, so that the symptoms presented were considered to be indicative of over work and loss of nervous energy rather than of any physiological disturbance The patient herself was disposed to consider her symptoms malarial in their nature, although, contrary to her expectations, quinine gave her no relief Occasionally, she would speak of her eyes smarting and watering if she tried to use them

Suddenly, on March 16, 1887, she was taken with out any apparent cause with headache, extreme nausea, and uncontrollable vomiting The usual antiemetic remedies, internal and external, dietary and medicinal, were tried in turn, but all without relief On the contrary, they seemed rather to increase her distress The only expedient that gave the slightest resemblance of relief was the holding of pieces of ice in the mouth The vomiting was almost incessant, and was increased by assuming the recumbent position The vomitus consisted at first of mucus, on the third day of free blood, and later of thick yellow bile Tenderness in the epigastric and right hypochondriac regions speedly developed itself The temperature and pulse remained nearly normal The nasal discharge was uniformly bloody The menstrual functions still remained normal so that the symptoms seemed to indicate clearly an acute exacerbation of the same trouble that had existed all winter in a mild and chronic form Although I could not absolutely exclude either a primary gastroduodenal ulceration or some of the freaks of pregnancy, I remembered the withering of the ferns and began strongly to suspect some form of irritant poisoning to be the cause of sickness I accordingly sent samples of all the wall papers in the house (except, of course, plain "cartridge" papers which I knew to be practically free from suspicion) to Dr Edward S Wood for examination Upon analysis, he pronounced only one paper arsenical, but found such an amount of arsenic therein, that he advised its immediate removal

To settle decisively the question of poisoning, the urine also was examined for arsenic Six ounces collected on March 23, the eighth day of the incessant vomiting, yielded numerous crystals of arsenic after re-sublimation in the tube, while a quart of urine collected three days later yielded a very dark deposit upon the tube, but after re-sublimation, scarcely a trace of arsenic crystals This seemed to indicate not only that there had been a very large amount of arsenic in the system of my patient, but also that a rapid elimination of the poison was taking place But the vomiting and prostration continued unabated For twenty days the patient could retain absolutely nothing upon the stomach Enemata, both of beef tea and of Murdock's food were attempted, but could not be retained Finally, brandy was substituted for them and with better results The temperature had never risen above 100°, nor the pulse much above 96 At midnight of the twentieth day the nausea and vomiting ceased as suddenly as it had begun The following morning the patient expressed her first desire for food We began with Horlick's Food, and although during the next week we changed at her request to Mellen's, Hard's and to Wells and Richardson's Lactated Food, we returned to Horlick's and found it the best suited to the case The recovery was rapid and complete in less than a fortnight There was only one relapse that could be traced directly to arsenic

It had seemed at first improbable not only to myself, but to Drs Wood and Whittier, whom I consulted in the case, that the wall paper already found to contain arsenic could be the sole cause of all this arsenical poisoning The paper was upon the walls of a small room on the entrance floor of the house where the patient had been very little, the parlors were on the floor above, and her chamber on the floor above the parlors In hopes, therefore, of finding some other source of arsenic, dress goods and window draperies were analyzed, but with negative results, so far as finding arsenic were concerned Chromium was, however, found in large amounts in one pattern of dark-green dress goods I had early seen to it that all cretonnes and turkey red material were removed from the chamber, since they are well known to be highly charged with arsenic The almost conclusive proof, however, that the sole cause of my patient's sickness existed in this room is as follows The dangerous wall-paper was removed while the patient was convalescent She insisted that she was not yet strong enough to venture from home and so remained in the house, confined strictly to her room, while the work went on After the walls had been scraped and washed, and the room thoroughly cleaned preparatory to the laying of the new paper, she ventured to look into the room, but remained there scarcely ten minutes She very soon had a return of nausea and vomiting, which lasted nearly twenty four hours I thereupon insisted that she go into the country, and that in her absence the entire house be thoroughly cleaned and dusted This was done, and since her return she has presented no further symptoms of arsenic poisoning

Another member of the family was affected by the removal of the paper, his symptoms taking the form of a sharp diarrhœa The other two members did not at any time present marked symptoms of arsenical poisoning, except a noticeably sallow complexion and a pretty constant feeling of lassitude all winter They had, however, had more exercise in the open air than my patient

I trust the record of this case may stimulate physicians to investigate more thoroughly than they otherwise might, cases that they hastly assume to be the results of malaria, nervous prostration or other indefinite or undetermined causes Many of these cases I believe to be simply chronic poisoning from some material source near at hand The profession has learned that wall-paper and some kitchen utensils are often arsenical, and it is slowly realizing that articles of clothing and of household decoration may likewise be injurious to health, although the subject has not yet received the attention that it deserves It seems to me that it is our duty, as physicians interested in public health and preventive medicine, to make renewed and concerted efforts to secure such laws as shall make it a criminal offense for a manufacturer to allow any deadly poison to be in fabrics or materials that are used or that are sold upon the market

DR B F DAVENPORT said It may be of interest to the Society to know, in connection with this case, that the German government has, during the past summer, passed a new law, to go into effect next spring, in which the presence of two and one half

grains of arsenic per square yard is allowed in woven goods, provided it is in an insoluble (?) condition The presence of arsenic in any arsenical color is forbidden if the arsenic is present as a constituent part of the color, but if it is present simply as an impure material, the law forbidding its presence does not apply What the grounds for these limits of the new German law are I do not know, but presumably they are placed on some competent experiment

DR F I KNIGHT asked if that would modify the law in relation to the manufacture of colors also

DR DAVENPORT Yes The old German law, which is at present upon the statute books, forbids the presence of arsenic in toys and wall papers, but its enforcement has been suspended, and they allow the presence of arsenic in other things, provided they are to be exported They are not so particular about other nations as about their own That reminds one of the oleomargarine law in one of the western cities The dairy commissioner, reporting on the subject, said it was immediately gotten rid of by shipping into the neighboring States

DR ALBERT N BLODGETT said I would like to ask Dr Smith what degree of reliability is to be placed on the testimony of paper manufacturers or paper dealers as to the presence or absence of arsenic in their manufactured fabrics A short time ago in a discussion before this Section the statement was made that the certificates of chemists were often utterly valueless, that paper which was pronounced by competent chemists free from arsenic was found to contain large and dangerous amounts of it I would like to ask if Dr Smith has had any experience in the proving of certificates of the chemists of manufacturers in regard to the compounds of arsenic in paper, and what value he places upon them

DR SMITH When I was re papering my rooms, I was in some doubt as to what dealer to go to, Bumstead, or Gregory & Brown I went to the latter, and picked out papers that I thought I would like, and saw the analyses The papers were said to be free from arsenic I did not engage them to hang the paper, but engaged a wall decorator, he traded for the most part with another firm, the Boston Wall Paper Company They had a chemist of whom Dr Wood and Dr Harrington had never heard They had specimens which were said to be free from poison I finally purchased of Gregory & Brown Dr Harrington had marked one specimen "Practically free from arsenic" I went to Dr Harrington myself, because I wanted to know how much it contained I should place very little reliance upon the statements of any dealer in wall paper, because he is in one sense an interested, and in another sense an uninterested party He may sell arsenical wall paper in perfectly good faith He receives it from the producer, and takes the word of the chemist If it proves to be full of arsenic, of course if there were a law, he would be subject to penalty

When I was getting the paper, Dr Wood told me an experience that he passed through He changed the paper in his house while he was at the sea shore Dr Hill one day asked him what paper he was putting on the dining room He replied that it was from a lot which had been examined, as the dealer said, by Dr Hill himself Dr Hill was sure he had not seen it before, and on analyzing it, it was found to be a typical arsenical paper Mr Bumstead had the paper taken off at his own expense, and Dr Wood said the paper hanger had the most typical case of inflammation about the nails that he ever saw I think Bumstead although he has made some mistakes that were reported here last winter, has always acted fairly when he has found any paper that contained arsenic I am sure that Gregory & Brown are very careful

DR DAVENPORT said It is well to remember that the certificate of the chemist applies only to the particular sample examined It does not apply to another roll, whether of the same pattern or not Two rolls of the same pattern may be quite different One may be free, the other may contain a considerable amount of arsenic

DR SMITH The reason why I spoke as I did about the law was because Dr Wood said he had been at the State house, in relation to the matter, but has been rebuffed every time Testimony is brought forward to controvert his own If the law were passed, he would be cutting his own fingers, for he gets some income for analyzing the papers He has been one of the most strenuous in pushing the law at the State house I would like to ask Dr Davenport whether arsenic in wall paper does not exist for the main part as an impurity

DR DAVENPORT I presume it does Most wall paper in this vicinity is manufactured by the American Wall Paper Company They claim, and with reasonable evidence in favor of it, that they do not now use arsenical colors at all and do not intend to have arsenic in their paper I have understood that they had last year a thousand samples of paper, just as it came from the factory, analyzed, and they found that it contained arsenic on the average in some 66 per cent of samples

The stock from which the paper is made is largely clay, and this, as well as the ochre, may contain arsenic All papers with gilt contain arsenic, that is, practically all, because commercial copper is very seldom free from arsenic Of course the bronze contains copper and zinc Gilt from the American ore is generally free, but imported ore generally contains arsenic Then, as all chemicals are made more or less directly with the use of sulphuric acid, which is made from pyrites, it may come in that way And so, well nigh everything, unless it has been specially freed from it, would contain a trace of arsenic

DR SMITH said It seemed to me that the amount of arsenic which would thereby creep into the color would be very small, but I supposed that the arsenic was used as a mordant, and was not washed out

DR DAVENPORT As a mordant, quite a number of large cotton print mills use twenty tons of arsenic a month A common piece of print cloth may contain three, four or five grains of arsenic per yard

DR SMITH had been told last June that Mr Binney, employed by the Walpole company, made the strong assertion that arsenic had no business in the

chemistry of coloring material at the present time, that it was the lazy greediness of the manufacturers, who allow it to remain in their colors, that they do not take time to wash it out thoroughly

DR BUCK said There is one element of danger in papering rooms which does not often come up here We may have a paper perfectly free from arsenic, and still get arsenic poisoning A certain number of paper hangers put arsenic in their paste, and that gradually gets through the paper I would like to know if any one has seen differences in the number of cases reported in different seasons of the year In my experience, I have seen more cases in the summer than at any other time I have seen many paper box workers during the summer, and although I have had the dispensary work to do at other seasons of the year, I have not seen these patients during the winter or fall months They have presented themselves chiefly during the early summer I have thought that possibly it might have something to do with the heat, there being a greater degree of volatility at that season of the year

DR VICKERY Would paper containing two thirds of a grain to the yard be poisonous?

DR DAVENPORT Whether it would be poisonous is a question of dispute Some say yes, and some no Nobody knows

DR BLODGETT I would like to observe that the chemist of the Roxbury Carpet Works, in which nearly all of the various colors are employed, informed me that he never used arsenic, and that it was entirely unnecessary and out of place in the production of any color, and that it was perfectly possible to get all the advantages found in arsenic from other and safe means He expressed himself very strongly, and said that the presence of arsenic even as an impurity was unnecessary if proper care was employed in the selection of colors

DR SMITH added that a former occupant of the house where this patient lived had died from some obscure trouble, having had stomach and head symptoms She supposed it was the drainage, and the plumbers had been over the house again and again, but they pronounced everything in good order Perhaps the present case may give us some hint as to the cause of that sickness and death

DR PENGRA In what form is the arsenic set free from the wall papers? Is it in the form of gas or solid?

DR DAVENPORT I believe it is now commonly considered that the danger is from the dust which is removed from the surface and inhaled It was claimed at one time that there was danger of arseniuretted hydrogen being formed and inhaled as a gas I believe the latest experiments have shown that this gas is not formed except there is free arsenic present in the color In the case of Scheele's green or Paris green, each commonly contains a certain per cent of free arsenic, so that in the presence of moisture and fermentation, arseniuretted hydrogen may be formed In connection with those hearings which were carried on before the legislature, one of the gentlemen papered a large room with a heavy arsenical paper, and drew the air from the room through a solution which would take out the gas which would be formed I think it was carried on for some weeks without any result

DR PENGRA I would like to know whether the finish would not have something to do with it

DR DAVENPORT As I understand it, the danger is of the color being mechanically removed Of course if the finish is such as to prevent that, the danger is prevented A rough finish, I presume, is more likely to be loosely attached than the smooth polished surface There are a great many interesting questions arising from this Take a paper which contains a grain of arsenic per square yard Suppose that it covers a room larger than the average, so that we have sixteen rolls of paper Such a room would have something like sixty grains of arsenic on the wall It would take a good many years for the paper to fall off, and if one were in the room and inhaled all of it, it would be a very minute quantity It seems as if people were more affected by very minute doses than we are accustomed to see when we give it medicinally One writer says that it has a greater effect, but I do not know why

DR PENGRA said I would agree with Dr Davenport's statements that the arsenic would not become arseniuretted hydrogen, but the process of fermentation may produce that gas During the past four years I have seen students to the number of from one hundred to two hundred, working in a laboratory where the gas was generated every day, each student probably generating from six to ten volumes in a moderate sized room They did this during six to nine months of the year I have never seen a student suffering from anything like arsenic poisoning I have seen students suffering from the fumes of amyl alcohol and from sulphuretted hydrogen, but never has there been a case of arsenic poisoning among students who have been there two years

(To be concluded)

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

How Medical Men can Aid the Health Authorities

There has been nothing more encouraging for a long time in matters pertaining to public health in this city than the appearance, recently, of Dr Bryant, one of the Commissioners of the Metropolitan Board of Health, before the Academy of Medicine to ask for the cordial support and cooperation of the medical profession, and point out in a concise and emphatic manner the ways in which this end could be most satisfactorily secured This event was rightly regarded by some of the speakers who took part in the discussion on this occasion as inaugurating a new era in the sanitary history of New York As one of them, Dr Andrew H Smith, remarked, there have not in the past been those cordial relations between the profession and the Health Department that should have existed, and the latter has often

been regarded very much as an athlete who struck out from both shoulders, seeming to direct its blows on the one side against the public and on the other against the medical profession Dr Smith said that he had always believed the Board of Health should be the outcome of the profession and be in full sympathy, and that he could not but feel that Dr Bryant's address would be of great service in promoting the sentiment of a community of interests between the two When medical men could feel convinced that the Board was really a part of the profession, its usefulness would be greatly increased, and he had little doubt that, from this time forth, such would actually be the case

The subject of Dr Bryant's paper was, "How can the Profession Aid the Board of Health?" While there ought undoubtedly, he said, to be the most complete harmony between the two, and they should labor together, with common purposes, this had hitherto by no means always been the case, and they had, as a rule, been much greater strangers to each other than should have been the case He first gave a sketch of the organization of the Board under the recent head of the Department, General Shaler, in which there were seven divisions, all subject to a semi military system From a practical point of view, however, this system was found to be more ornamental than useful, and circumlocutory rather than thoroughly efficient

Dr Bryant then spoke of the present organization of the Board, and described the more important changes which had been introduced under the administration of President Bayles, who was present by special invitation and addressed the Academy later in the evening Among these changes was the relieving of the medical officers of the Board from the duty of making general inspections, and which is now performed by a corps of lay and police sanitary inspectors There are 45 members of the sanitary police corps, each having charge of the inspections in one of the 45 districts into which the city is divided, and it is their special duty to systematically and thoroughly inspect all the tenement houses in their respective districts The lay sanitary inspectors are 15 in number, one to each of the 15 larger districts into which the city is divided, and it is their duty to make inspections of buildings other than tenement houses, to investigate complaints made by citizens, and to deal with problems too deep for the sanitary police, by whom such problems are referred to them All the medical sanitary inspectors are now detailed to the department of contagious diseases, and it is their duty to at once visit the locality of any case of contagious disease reported to the Board, and see that proper measures for isolation, disinfection, etc, are promptly carried out When in any instance it is found that suitable medical treatment cannot be pursued, or that isolation of the patient cannot be secured, they advise that the case be removed to the hospital They are especially charged that they must cooperate in every way with the medical attendant in charge of the case, and are always to treat the latter in accordance with the recognized principles of professional etiquette

The medical inspectors, Dr Bryant said, were thus restricted to work that was entirely professional, and the most ample opportunities were afforded by the present system for the scientific investigation of disease In order to further this object promotion and the increase of salary are made dependent on faithful and intelligent service, and in addition, the services of Drs J M Prudden, of the College of Physicians and Surgeons, and H M Biggs, of Bellevue Hospital Medical College, had been secured as pathologists of the Board In the bureau of vaccination and contagious disease in animals expert diagnosticians have also been employed Convenient and comfortable means are provided for the transfer of patients to the hospitals of the Board, and the admirably constructed Willard Parker Hospital, at the foot of E Fifteenth St, is fitted up with all the modern appliances for the successful treatment of disease It has accommodations for 75 or 100 cases of diphtheria or scarlatina, an efficient house physician, well trained nurses, and a medical board consisting of such men as Drs E G Janeway, Joseph O'Dwyer, A Jacobi, Stephen Smith, George F Shrady and D M Stimson The Reception Hospital, near by, is also under the supervision of the same medical board On North Brother Island are the fine new small pox hospital and five pavilions, each with accommodations for 25 or 30 patients, for contagious diseases other than small pox

At the present time, Dr Bryant went on to say, the Board was paying special attention to the treatment of contagious diseases, and the urgent necessity for this was sufficiently attested by the fact that from the 1st of January to the 1st of September, 1887, there were no less than 1,575 deaths from diphtheria reported in the city There was entirely too much indifference on the part of the public to such affections as diphtheria, whose widespread ravages are continuous in the community, while a single case of a disease like cholera, the prevalence of which would seriously interfere with its business interests, would at once cause profound excitement and receive the greatest possible attention The Board had great odds to contend against, as it was estimated that from 15 to 25 per cent of the cases of contagious diseases occurring in the city were never reported by the medical attendants in charge of them It was estimated that from 25 to 30 per cent of the births were also unreported

At the conclusion of his paper Dr Bryant suggested the following ways in which the medical profession could aid the Board of Health in its work

1 By reporting at once all varieties of nuisances detrimental to health or dangerous to life

2 By promptly reporting all cases of contagious disease In this way many valuable lives could be saved and epidemics could be averted

3 By enforcing strict isolation and employing suitable disinfectant and antiseptic measures in cases of contagious disease

4 By reporting all cases in which isolation cannot be secured or proper medical treatment be carried out

5 By visiting the Willard Parker Hospital and

thus being able to speak from personal observation of the advantages which it affords

6 By being careful not to send patients with contagious diseases to the dispensaries

7 By heartily cooperating with the medical inspectors of the Board in any case in which the latter are met with

8 By reporting all food or drink adulterations coming under notice

9 By reporting any instance observed of decaying fruit or other kind of unwholesome food offered for sale

10 By reporting all defects in plumbing, light and ventilation observed in houses visited

11 By paying special attention to the sanitary condition of the homes of patients

12 By promptly reporting all births This was of special service in securing the more general vaccination of infants

13 By the appointment of a committee of physicians, not less than five in number, to confer with the Board of Health, whenever such conference seems desirable, on all matters pertaining to the public health

At the end of the meeting a resolution was adopted to the effect that the President, Dr Jacobi, should appoint a committe of five Fellows of the Academy, of which he (*Dr Jacobi*) should be one, to confer with the Board of Health in the manner suggested by Dr Bryant in his paper P B P

THE TREATMENT OF FRACTURES OF THE OLECRANON

Dear Sir —An editorial article in THE JOURNAL of last week, under the above title, recalls a device for maintaining apposition of fractured olecranon which I have found useful, and which may be thought worthy of adoption in the treatment of this fracture and that of the patella

The evidence of its utility rests upon only one case of each kind, but the first afforded a fairly crucial test, as the subject was a very muscular young man, and the wide separation of the olecranon from the shaft of the ulna—nearly an inch—showed that the periepiphyseal fibrous tissues had been wholly disrupted The injury was dressed immediately after its occurrence in the following manner

A thick shellac felt and splint was moulded to the anterior surface of the arm and forearm in extension, reaching from near the wrist to near the shoulder Enough padding was employed to insure an unobstructed circulation under a tight dressing A piece of tin about fourteen inches long and three fourths of an inch wide was bent flat upon itself at one end, to hook over the lower end of the splint, which was then applied, the strip of tin lying along its external surface The tin was then bent out at right angles at a point about four inches below the olecranon, after which a firm muslin bandage was applied, beginning at the hand Upon reaching the angle in the tin, the roller was carried over the upper fragment in successive loops, each brought down to the angle and secured by one or more circular turns Then the customary spiral turns to the shoulder were applied Finally, the free end of the tin was bent back so as to draw more terse, if possible, the coaptation loops, and a few turns of bandage fixed it securely

The dressing remained unchanged for a week, when it was partially removed and tightened a little by bending back the tin a trifle, although no separation had occurred, nor at the end of the second week, when passive motion was cautiously made At this time I lost sight of the patient, who resided in a neighboring State, but the physician who had the final charge of him wrote me that the olecranon adhered perfectly, and evidently by bony union

With many surgeons it is a grave objection to the adhesive coaptation strips that, if efficient, they cut into or inflame the integument at the point of pressure over the olecranon

With the muslin bandage this does not occur Its hold at the insertion of the triceps is sufficiently secure, and with the tin-loop point of resistance, the completed dressing must be as firm as that of M Fraipont Moreover, there is the additional advantage that it can at pleasure be tightened *in situ*, without disturbing it more than to undo the last few turns of bandage J R. BARNETT, M D

LITHIASIS IN PREGNANCY

Read in the Section on Obstetrics and Diseases of Women, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY J E. KELLY, F R C S I, M R I A,

OF NEW YORK

LATE SURGEON TO JERVIS STREET HOSPITAL PROFESSOR OF PHYSIOLOGY, SURGERY ETC, DUBLIN IRELAND

When honored by an invitation to contribute a paper to the proceedings of the Obstetrical Section of the American Medical Association, I was anxious to select a topic which, while possessing some novelty and belonging to the wider domain of General Medicine, might be useful and pertinent to the subjects within the province of this department

It is some years since first I observed the frequent manifestations of certain symptoms during pregnancy, and their subsequent persistence, that could be explained most satisfactorily by ascribing them to the influence of the lithic acid diathesis Additional observation and reflection having satisfied me that the association was more than coincidental, I have concluded to submit my speculations to the consideration of this Section That many observers have noticed the association of lithiasis with pregnancy is beyond question, but I am not aware of any attempt to present the facts and inferences in continuity It is not so evident, either, that the profession generally has recognized the affiliation or the tendency which the phenomena of gestation have to develop this dyscrasia My intention is to review the characteristics of lithiasis, their analogous manifestations in pregnancy with the physiological processes in the last mentioned which favor their development, and thus I shall endeavor to establish a definite relation between the two conditions

For the sake of continuity I will briefly recapitulate a few generally recognized principles concerning lithiasis It is a diathesis associated with the presence of an excess of lithic, or uric acid in the system, and made manifest by very varied phenomena, affecting almost every structure and function Uric acid is derived from the proteid tissues and from the albuminous or nitrogenous foods The manner of the formation of uric acid is a subject as yet involved in much obscurity, but it is generally conceded that, when it exceeds the normal quantity, marked disturbance of the structure or the functions of one or more important organs is the result Primarily or secondarily the liver, stomach, kidneys, nervous system, lungs, and the blood are severally or collectively involved, although in many instances no departure from the normal condition can be detected in some one or more of these factors Lithiasis is intimately associated with those important excrementitious substances, urea and the urates, which result from and, other things being equal, represent in constant proportions the constructive and the destructive cell-changes of the system The intermediate link between the presence of uric acid and the manifestations of lithiasis is the deposition of the former in the affected tissues or of the salts produced by its combination with some of the inorganic elements, notably that with sodium The resulting disturbance of the functions or the nutrition of the invaded organs produces the symptoms of the diathesis, and verily their name is legion

The specific gravity and the alkalinity of the blood is diminished and the excrementitious matters, especially the uric acid and the urates, are increased in quantity, the alkalinity of the blood is less than normal and the fibrin is increased The objective symptoms of anæmia also are frequently present and, naturally, they are associated with a reduction of the red corpuscles The results of these abnormal conditions of the blood are very numerous, eczema, pruritus, phlebitis, neuralgia, myalgia, œdema and dropsy being prominent among the many In the vascular system the arterial tension is increased and cardiac hypertrophy, simple or complicated, is a frequent consequence Palpitation, irregularity of action, syncope and other diseased cardiac conditions are often present

It is reasonable to suppose that respiration is involved in an important manner, as uric acid is the result of arrested oxidation of the nitrogenous elements which otherwise are convertible into the easily eliminated urea The most frequent examples of disturbance of the respiration are dyspnœa, irritable cough and hiccough

The connection between lithiasis and the digestive system is close, and its manifestations are marked and frequent Without dwelling upon the causal influence of gastric acidity and imperfect digestion, we must notice their frequency in lithiasis The various actions and secretions are deranged, producing morbid appetite, gastralgia acid and other eructations, nausea, vomiting, irritative diarrhœa or constipation, tympanites, hæmorrhoids, and several other symptoms

The liver suffers more from functional than from structural derangement, although inflammatory changes are not infrequent We must not forget that one of the best sustained theories of lithiasis attributes this morbid condition to the functional disturbance of this organ, and we also witness biliousness, jaundice, and hepatitis That the spleen is involved in lithiasis is indicated by the constant presence within it of a large quantity of uric acid

The relation between lithiasis and the kidneys is universally recognized, although in some rare instances no structural changes can be detected As a rule, however, some of the varied phenomena of inflammation, from hyperæmia to cirrhosis, degeneration or a deposition of the solid constituents of the urine can be demonstrated, and the character of that fluid is greatly and variously modified The phenomena associated with the urinary organs are too numerous to be detailed, but in definite relation with lithiasis are abnormal polyuria and diabetes, suppression and retention of urine, irritable bladder and cystitis

Numerous nervous phenomena appear in lithiasis which may be collectively attributed to the development of increased irritability and malnutrition Psychical, sensational, spasmodic and trophic phenomena are constantly witnessed and appear to stand convertibly as cause and effect with the disease Manifestations of these nervous perturbations are frequently witnessed in the form of convulsions, cramps, myalgia, neuralgia, hysteria and mental aberration

The changes produced by lithiasis in the skeletal structure and those of the connective tissue series generally, are characteristic The bones suffer by the formation of nodes, laminæ and exostoses, the ligaments and fasciæ by the deposition of the urates and the consequent inflammation, contraction and rigidity The synovial membranes are affected with inflammation, adhesions and induration

The influences which predispose to lithiasis are many, and it would appear that a marked departure, either idiopathic or acquired, from the normal standard of the function of any important organ determines its development It is also significant that the influence of a single manifestation of lithiasis is liable to be followed by serious and far-reaching consequences, indicating the establishment of the diathesis

If we now turn our attention to the phenomena of pregnancy, we cannot fail to observe a remarkable coincidence between the diseases as well as the pathology of that condition and of lithiasis All those features to which I have alluded when reviewing lithiasis are frequently seen in pregnancy The structural changes which are present in the former are of common occurrence, and the physiological conditions of gestation are favorable to its development In the etiology of the two classes of diseases the parallel is sustained, as in both we have the same hæmic influences, the same irritable or "explosive" state of the nervous system, and the same renal and digestive disturbances In pregnancy we find additional and potent factors in the increased metabolic energy, and the mechanical conditions which, if present in a lithæmic individual, would most probably contribute to the development of the disease Those morbid conditions which are ascribed with the greatest confidence in pregnancy to the mechanical factors, as venous dilatation, œdema of the lower limbs and the genitals, hæmorrhoids, retention and irritable bladder, are frequently seen also in gouty males and non-pregnant females

The condition of the maternal blood in gestation is in keeping with the physiological relation which exists between the mother and the development of the fœtus The cell changes of the composite animal are increased proportionately with the growth of the fœtus and the containing uterus The fœtal organs, with the exception of the heart and liver, are practically inert, and the double duty is imposed on the corresponding maternal organs The medium through which these additional functions are performed is the maternal blood, and consequently the quantity of the nutritive and the excretory substances conveyed by that fluid is necessarily increased and, owing to the greater constructive and metabolic energy exerted during the process of development, increased most probably in more than in the ratio of the dimensions of the utero-fœtal mass to the mother The chief nutritive and excretory matters circulating in the blood are nitrogenous and inorganic, and consequently are most conducive to the development of lithæmia, as well as of puerperal septicæmia, eclampsia, peritonitis and thrombosis The alkalinity of the blood which is so essential to the solution of the lithic acid compounds is diminished Owing to the reduction of the number of the red corpuscles, together with the constant absorption of the nutritive materials by the exacting fœtus, hydræmia frequently exists The consequent tenuity should be additionally favorable to the deposition of the uric acid and the urates The increased quantity of fibrine which has been observed during gestation may afford a clue to some cases of cardiac disease, as well as to the not unusual occurrence of embolism and thrombosis It may be permissible to speculate upon the possibility of those conditions, which the fœtal fluids would naturally share with the maternal blood, affording a clue to the etiology of some of those obscure cases of intra-uterine deformities and disease, as well as of congenital cardiac lesions and adherent placenta, depending upon plastic and inflammatory changes of the serous and enveloping membranes of the fœtus

In the vascular system the most constant results of pregnancy are the increase of the arterial tension and of the cardiac action The cause of these conditions in the earlier months of gestation is rather obscure, but as pregnancy advances it becomes very obvious The increased quantity of fluid which the heart must propel, the augmented functional activity of the kidneys and the other maternal organs, the additional resistance which is offered by the utero placental circulation, which may be largely due to the osmotic process in the placental circulation during the interchange of the maternal with the fœtal blood, all contribute to throw more labor upon the heart This organ is stimulated to greater rapidity of action in the entire 24 hours by the profuse cell

changes in the nutritive and excretory organs of the two systems and by the elevation of temperature in the uterine circulation I may mention incidentally that the abeyance of the phenomenon of the decrease of the beats on the assumption of the sitting or the recumbent posture has been recently proposed as of diagnostic value in cases of obscure pregnancy, which I have verified as early as the second month The result of the additional strain is conservative hypertrophy of the heart The form of hypertrophy is a matter of speculation, and whether it is simple or eccentric is a question of interest both to the physiologist and to the physician Another natural result of this condition is the more forcible action of the heart and an increase of the violence with which the valves and the other mechanical structures perform their functions This violence is liable to produce local inflammation at the points of areas of valvular impact or contact and at the sites of traction of the chordæ tendineæ These localities are thus prepared for the deposition or the infiltration of the morbid elements of the blood, with consequent stenosis and valvular insufficiency The resulting irregularity or roughness of the endocardium also affords a suitable surface for the deposition of the so called "vegetations" to which the excess of fibrine is peculiarly favorable These conditions may be independent, or associated with the results of the hypertrophy, which may be followed, like the uterus, by normal involution or the analogous conditions of subinvolution, or that which is rarer, superinvolution, thus producing simple or complicated cardiac hypertrophy or weakness with or without dilatation Again, if the process of involution be rendered abnormal by the presence of lithiasis or some other disturbing influence, the result may be fatty, calcareous or other cardiac or vascular degeneration To the last specially mentioned condition the discovery of lacunæ of calcareous matter in the organism of the pregnant female would indicate a special tendency The heart suffers mechanically also during gestation by the encroachment of the gravid uterus on the thoracic cavity, as is evidenced by the palpitation which is sometimes produced when the pregnant female assumes the recumbent position, and which is rapidly relieved by change of posture

The influence of gestation upon the respiration is not as distinct as upon the other functions, but although a certain compensatory change occurs in the shape of the thorax by its increased antero posterior and transverse dimensions, it is obviously disturbed by the growth of the uterus, and the inspiratory and expiratory movements must be diminished The most marked change in the expired air is due to the increased elimination of the carbonic acid, and probably of the water which is a natural consequence of the respiratory needs of the second organism The most frequent disturbances of respiration are dyspnœa, hiccough and irritable cough A particular interest is attached to the fact that physiologists have recently localized the centre which is supposed to preside over the formation of uric acid at a point close to the respiratory centre in the floor of the fourth ventricle That this has any practical bearing upon our present investigation is not very evident, but when the principal difference between uric acid and urea is the lesser atomic combination of oxygen with the former, the relative position of the two centres may have some causal relation to the presence of the acid in pregnancy

The phenomena presented by the chylopoetic system in pregnancy are so numerous and important that we can only briefly indicate their relation to our subject In the first instance we find that as gestation advances the pregnant woman generally consumes a greater quantity of food and of a more varied kind, a circumstance which is notorious for its association with the gouty diathesis She also suffers from functional dyspepsia, cardialgia eructation and vomiting The success which so frequently follows the exhibition of anti lithic remedies in such cases tends to indicate the nature of these disturbances The intestines furnish us with additional links for our chain of evidence by the occurrence of diarrhœa, often of an irritative character, and of constipation symptoms which are frequent in lithiasis

The hepatic disturbances are additionally interesting owing to the weight of evidence which has been adduced to convict the liver of being the chief offender in the production of the lithiasis There is undoubtedly more than a causal relation between pregnancy and hepatic disturbance as is evidenced by the frequency of pigmentation and jaundice, acute yellow atrophy of the liver, a disease which is associated with gestation with significant frequency This fatal disease, as well as some other hepatic lesions, is additionally interesting in our present speculation owing to its causal relation, which it shares with pronounced lithiasis or gout, to grave nervous depression, emotional disturbance and bad hygienic surroundings

The mechanical influence which the gravid uterus exerts on the digestive organs is easily recognized with regard to the gastro intestinal tract, but unless obstructive jaundice is produced in the later months of gestation by the traction of the biliary ducts consequent upon the upward displacement of the liver, it is difficult to recognize it as an important factor It is hardly possible for the biliary ducts to be compressed in the carefully protected position which they occupy, first, in the transverse fissure of the liver, guarded by the lobulous quadratus and in front of the vena cava, then in the lesser omentum behind the duodenum, and lastly, between the heart pancreas and the second portion of the duodenum It is more probable that this phenomenon is the result of direct pressure upon the liver, or some coincidental disturbance attributable to the dyscrasia or to an occult reflex nervous influence So little is known of the spleen and its relativities that we cannot expect to establish a definite connection between it and the diseases of gestation, but in that rare disease, leucocythæmia, we find that a very large proportion of the cases occurring in females are associated with pregnancy

The influence of gestation upon the urinary organs is very marked owing to their anatomical association as well as to the important duties which they perform as the chief emunctories of the system The quan-

tity of urine is notably increased and the total amount of the excreted solids is greater than in the non-pregnant state The changes which take place in the kidneys vary from slight and transient hyperæmia to the acute and chronic parenchymatous nephrites of pregnancy Almost all the pathological changes to which the kidneys are liable are associated with gestation, but those which are most frequently present are such as are usually found in lithiasis It has not been demonstrated that renal hypertrophy accompanies normal gestation, but from analogy with the conservative changes which take place in the abiding organ when one kidney has been extirpated, or destroyed by disease, we would expect to find compensatory enlargement owing to the greatly increased functional labor of these organs We are familiar with the idea that renal disease is easily induced in those individuals upon whom nature has bestowed organs which are barely adequate to their ordinary necessities When any unusual strain is put upon them by exposure, disease, rapid increase of weight, or overwork, the mediocre organs fail, and we have another example of the close relation which exists between weakness and irritability or disease That such a strain is considerable in pregnancy is very obvious, arterial tension is increased, the amount of solids and fluid passing through the organs is greater, of the total vital force they experience a diminished influence and the disastrous results are only too frequent It is very probable that the so called puerperal diseases of the kidneys originate during gestation, and that the evil effects have only culminated when the additional strain of parturition is imposed upon the diseased and incapable organs

The theory of the mechanical influence of the gravid uterus by its pressure on the renal veins has been ably refuted by more than one observer, with whom, upon anatomical grounds, I entirely agree, but I consider it more than probable that the ureters are subjected to such interference in the lower portion of the abdominal cavity where they lie on the psoas muscles or in the cavity of the pelvis in close contact with the cervix uteri, and where every modification of position and dimension must produce mechanical effect The results following the ligation of the ureters in the inferior animals, which produces grave structural changes in the kidneys and the copious accumulation of the urates and uric acid in the blood and the tissues generally, clearly indicate the consequences of any mechanical obstruction This is most liable to occur in the later months of pregnancy or during parturition, and it may explain the appearance of eclampsia and other acute disorders, especially in difficult or tedious labors The remarkable absence of the elevation of the general temperature during the greatly increased metabolic activity of pregnancy, and notwithstanding the fact that the uterine temperature is higher than that of the system, may have some connection with the great depression of vital heat observed after ligation of the ureter

The nervous system is peculiarly prone to abnormal manifestations during pregnancy The influence of this system over all other organs of the body and their reciprocal effects are too well known to require more than a cursory notice Morbid conditions of the blood exercise a marked effect upon the nervous phenomena owing to the consequent mal nutrition of the delicate nervous structures, and this may account for the frequency of nervous perturbation during gestation These nervous lesions which appear to have an etiological relation to this condition have already been mentioned in connection with lithiasis, but it is difficult to determine the proportion of causality to be attributed to the one and the other of those indissolubly associated or reciprocal factors The frequency of insomnia is interesting and may constitute a clue to the investigation of the purely nervous group of symptoms In the vomiting of pregnancy the closest investigation frequently fails to discover any cause other than a nervous influence, the nature and relations of which I have already discussed at some length in a paper entitled, "Causality in Disease," which appeared in the *Boston Medical Journal*, of April 15, 1886

I shall briefly refer to the conditions of the muscular and skeletal structures which we witness in pregnancy That condition which is termed mollities ossium, which is closely associated with child bearing, is peculiarly interesting as evidencing the powerful influence of the nutritive demands made by the fœtus on the maternal system In this disease the inorganic elements being supplied in deficient quantity by the digestive system of the mother, are absorbed from her bones and carried by the blood to the placental circulation The presence of rheumatoid and other arthritic lesions are notably frequent during the child bearing period and their occurrence after gestation is often observed The relation between these diseases and lithiasis is generally recognized and affords additional testimony in favor of the nexus which I am endeavoring to demonstrate The frequency of muscular rheumatism and spasm, or cramp, is also notable, and their association with lithiasis is well established

As in the *résumé* of lithiasis I wish to recall the persistent effects upon the system caused by the occurrence of a single pregnancy which manifesting themselves by various lesions not to be ascribed to any other other influence and indicating the permanent adoption by the constitution of a morbid action which must be regarded as being closely related to lithiasis In endeavoring to establish a parallel if not an identity between the constitutional tendency produced by lithiasis and pregnancy, I have indicated that both originate in a grave disturbance of nutrition, they present a similar modification of the blood, the pathological changes bear a close resemblance, the prominent functional disturbances are broadly identical, the numerous sequelæ are similar, and lastly, after one or more visitations the constitution is prone to adopt the induced condition as a diathesis

ECLAMPSIA

Read before the Section of Obstetrics and Gynecology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY WM T TAYLOR,[1] M D,
OF PHILADELPHIA

Therapeutics, like dress, has its fashion, and often the treatment of disease as well as the pathology will change with the times Nothing illustrates this better than the theories of its nature, and the treatment of eclampsia

During the first half of the nineteenth century, puerperal convulsions were treated almost exclusively by free depletion, and all the works on midwifery declared that that was the principal remedy, far superior to all others, but after awhile, in consequence of the do nothing system of Hahnemann, and the moral precept against the shedding of blood, which began to prevail amongst the people, the doctors laid aside their lancets—which they had always carried—and forgot their skill, so that as the late Professor Gross declared, "bleeding became one of the lost arts "

This is particularly unfortunate in the treatment of convulsions in childbirth, which usually yielded sooner to depletion, than by any modern improvement Although some cases do recover without blood letting, if they are well selected and properly understood, yet even they will bear some depletion, for in the formation of a new being, a large amount of blood is required for this work, and the mother will often lose a great quantity in childbirth, and recover rapidly afterwards

The subject of eclampsia has been written upon so often, that it has become a very trite theme, one on which very little new can be said, yet a *resume* of its pathology and treatment may not be objectionable at this time, when the medical pendulum is oscillating from one extreme to the other, and the treatment varies with the age in which we live

Eclampsia, which may occur to parturient women during the later months of gestation, or when in labor, is so named from the Greek $\epsilon\pi\iota\lambda\alpha\mu\beta\omega$, to flash out, because of the suddenness of its occurrence

It is very rare, if it occurs at all, amongst the Indian Tribes, for Dr Engleman does not mention it in his "Labor among Primitive Peoples," so that it must be regarded as one of the results of civilization, and a violation of nature's laws, during gestation, and in fact, from puberty when young women are put in tight fitting dresses and corsets, which prevent a full development of the abdominal and pelvic organs, and also as Dr Goodell has shown in his address on "The Dangers and Duty of the Hour," that faulty system of female education when the excessive brain work of young women often injures and prevents physical and sexual development Then when gestation and labor occurs the overacting brain becomes engorged with blood, and if not relieved by suitable remedies eclampsia may occur

Puerperal convulsions are either *sthenic* or *asthenic* Hippocrates considered them "to take place from repletion or depletion," they are therefore caused by plethora or anæmia, for an overflow of blood may produce convulsions, as in apoplexy, or an exsanguineous condition of the blood vessels may cause them when persons or animals are bled to death, so that the same condition may arise from opposite means, hence, the treatment must be governed accordingly

It is a curious fact, says Ramsbotham, that the two perfectly opposite states, viz, too great a fullness of the vessels, and too great emptiness, will produce in this respect exactly the same phenomena, and I look upon a case of puerperal convulsions to be in fact, one of apoplexy, only that we have superadded to the common apoplectic phenomena violent spasmodic contractions, and this symptom is dependent upon the irritable and excitable state of the nervous system, always in a greater or less degree accompanying pregnancy and parturition

As these convulsions arise from two distinct, and opposite conditions of the system, one in which excessive distention of the blood vessels of the brain or spinal cord, or both produce eclampsia by compression, the other, in which from excessive loss of blood, from hæmorrhage, natural or artificial, the nerve centres are drained of their blood, giving rise to convulsions from anæmia, as first pointed out by Marshall Hall In the one case bleeding is remedial by relieving the oppressed nerve centres and restoring the balance of the circulation, while in the other it only increases the evil Another most important and frequent cause is in the constitution of the blood, which becomes changed from its normal condition during utero gestation, by the mechanical pressure of the gravid uterus or the intestines, the renal vessels, nerves and kidneys, and the upward pressure against the diaphragm prevents its free action, and the perfect oxygenation of the blood, which then becomes a morbid stimulant to the nervous system in consequence of the albumen in the urine, and the retention of urea and other salts in the blood

The frequency of convulsions in primipara is owing to the fact, that the pressure is greater against the kidneys and renal vessels, in consequence of the rigidity of the abdominal walls, whilst in subsequent pregnancies the muscles are more relaxed, and consequently the congestion of the kidneys is not so great—for that is the chief cause of albuminuria in eclampsia, for this condition of the urine always exists in puerperal convulsions, as has been proved by Drs Lever, Simpson, and subsequent writers on the subject

Professor Braun, of Vienna, referring to the coincidence of eclampsia and albuminuria, says, "that this has opened a new path to the knowledge of this most dangerous disease, so that the eclamptic convulsions of women during pregnancy, must be considered to be identical with the fits of adults, in general, that are produced by uræmia in the course of Bright's disease

Frerichs conjectured that eclampsia was caused by the changing of the urea into carbonate of ammonia in the blood, and that this was the cause of

[1] Deceased

the death of the fœtus, but of this he gave no proof, and Dr Hammond, by experiment, has disproved this theory

At a recent meeting of the Société de Biologie, MM Doleris and Butte communicated the results of some chemical and experimental observations on five patients with eclampsia, and found in the blood a crystalline substance, which was toxic to rats and sparrows in almost infinitesimal doses, and that the proportion of urea in the blood was not excessive, its amount being too slight to attribute to it the cause of eclampsia

From all the information we have on the subject, we must necessarily come to the conclusion that the cause of puerperal convulsions is undecided, and it is yet *sub judice*

Dr T G Thomas says, that eclampsia differs from epilepsy, for the latter generally has an "aura" or warning like a cold vapor or sensation which arises from some part of the body, and proceeds to the head, when unconsciousness occurs, and the subject falls in a fit—being affected with clonic spasms, or alternate action of the flexor and extensor muscles, whilst in eclampsia there is a rigidity of the limbs, which are extended and bent backwards as in opisthotonos Epilepsy also occurs in both sexes He considers eclampsia to be caused by a nephritis which he calls puerperal, as it arises only during utero gestation, leaving the blood surcharged with some noxious elements which the crippled kidneys cannot eliminate, whilst we know not how this nephritis is produced, yet when gestation ceases to progress the renal trouble soon disappears The eccentric form of eclampsia may be caused by some reflex action arising from some irritation of the uterus or its appendages, the bladder, kidneys, stomach or bowels, for when these viscera are relieved the convulsions will often cease

They may also be caused by some atmospheric influence, and some writers say that they are more frequent when there is "thunder in the air," for then it is more highly charged with electricity An instance of this kind occurred in my own practice, when an attack of eclampsia was ushered in by a vivid flash of lighting, and a loud clap of thunder preceding a storm

The premonitory symptoms are headache, giddiness, drowsiness and a feeling of intoxication, with a staggering gait, a ringing in the ears, a dimness of vision, and even a total loss of sight, a numbness of the arms and legs, with difficulty of articulation

Stout, fat, able bodied women with short neck, swollen limbs and bloated faces are particularly liable to these convulsions, and if there is diplopia with flashes of light, a sudden loss of hearing with a feeling like a sudden blow on the head or a severe sudden pain in the stomach, the attack is imminent Then unconsciousness occurs, the face becomes red or purplish, the conjunctivæ are injected, and the pupils fixed, a violent jerking of the muscles of the upper and lower extremities takes place with a rotation of the head to one side, more often to the left, has been my observation There is also a horrid distortion of the face, with rapid breathing, causing at times a loud hissing sound The tongue is often thrust between the teeth and severely bitten, so that the bloody froth and saliva, which issued from the mouth of the patient when writhing in these contortions, presents a horrible scene to the attendants and friends

After a short time the fit passes off, and the woman may recover her consciousness slowly, but is not aware of what has occurred, yet complains of her head, and soon the convulsions may return with a repetition of the same condition, or she may remain comatose, with dull heavy stertorous breathing during their intermission The uterine contractions will continue, and the child may be expelled from the womb without her consciousness returning, or even the attendants being aware of it, until it is seen or felt between her thighs, it however, is generally dead

If the coma continues the danger of a fatal termination to the case is greater than when there are intervals of consciousness between the fits

As to the treatment it depends on the character of the convulsions, and the views the obstetrician may entertain of their pathology But in the hyperæmic cases when the pulse is full and hard, the most rational plan is to bleed promptly and freely at the beginning of the attack, so as to make a decided impression on the circulation, which alone can indicate the amount to be taken, and therefore the pulse should be watched As the majority of cases of eclampsia are in primipara, the rule is to bleed, for as Dr Goodell says, "an early, timely and full bleeding invariably relieves intra cranial pressure, whether caused by an effusion of blood or serum," and Dr Packard related a case to the Obstetrical Society of Philadelphia, of convulsions and death from apoplexy in labor, which was not bled, and the autopsy showed the meninges of the brain to be deeply congested, and all the tissues of the brain exceedingly vascular In the majority of cases of eclampsia the symptoms so strongly resemble those of apoplexy that venesection, either general or local, is not only advised, but absolutely required, even if other remedies are used

After depletion an enema of castor oil and turpentine will be useful, and if the stomach is loaded with food an emetic will be necessary, whilst cold should be applied to the head and neck, and the extremities kept warm When the fit is on we should prevent the patient from injuring herself, by restraining her from falling from the bed, or from striking her head or arms against any hard substance, by placing something between her jaws we prevent her biting the tongue, which is often seriously injured by getting between the teeth Slapping the face with a wet towel will sometimes excite inspiration, and arrest the convulsion

A vaginal examination should be made, and if the head has descended within the pelvic canal, deliver as quickly as possible with the hands or forceps, but if the paroxysm has subsided, trust to the uterine action to effect delivery, unless the presentation is abnormal After bleeding, inhalations of ether or chloroform are useful—an injection per rectum of

chloral hydrate, or a hypodermic injection of morphia

These remedies each have their advocates, who rely on them wholly without venesection, but I believe that the *asthenic* cases *only* can be cured without depletion, for in such there is not that intense pain in the head, which causes the woman to scream out violently—no redness of the conjunctiva, nor full, hard, throbbing pulse, but an anæmic condition of the system when bleeding may be omitted

Such cases can be relieved by inhalations of ether or chloroform, with injections of chloral repeated from time to time when the convulsions return As soon as the patient can swallow she should be given bromide of potash to allay nervous irritability If labor begin, promote delivery by all proper means, but if the fits have ceased and the uterus is quiescent, let it alone and wait for its action, which may not occur for several days, or even weeks after We should, however, improve the condition of the blood by the use of iron and tonics, with diuretics to act on the kidneys, of which nothing is better than Basham's mixture

Some cases which have occurred in my practice will be related

A young married woman of plethoric habit, had been affected with headache during the latter part of her first pregnancy, which was relieved somewhat by a purgative, and the application of cups to the back of the neck, was suddenly seized with a convulsion at midnight, when a neighboring physician was called on the emergency On my arrival I found her unconscious, with a full, hard pulse, and stertorous breathing She was bled freely, about two pints being taken, which relieved her breathing, and reduced her pulse, which became quite soft and compressible This arrested the convulsions, only occurring during the depletion, she however remained unconscious An injection of spirits of turpentine ℥ss with warm molasses and water was given every two hours, until she had a copious evacuation from the bowels, and cold was constantly applied to the head On vaginal examination there was no sign of labor, and as there were no more convulsions and she was breathing easier, we allowed her to rest On the next morning the os began to dilate, and in a few hours it was fully expanded, but as the expulsive pains were feeble and ineffectual, I applied the forceps and delivered her of a dead babe An anodyne of morphia, valerian and camphor was given to produce sleep, but she did not recover her consciousness until the following day, being unaware of what had occurred during the previous forty eight hours, her diminished abdomen alone revealing to her the birth of her child From this time she recovered perfectly, and although she has had several children since, yet has had no more attacks of eclampsia

J K, after an easy labor, gave birth to a child at 5 P M, the placenta coming away without any assistance, but the hæmorrhage was very slight At 8 P M she complained of pain at the epigastrium, with eructations, which were relieved with sulph morph in aq camph She slept some but at 2 A M she suddenly gave a sharp scream and had a fit of eclampsia, which was followed by others Being summoned, I bled her copiously and had cups applied to the back of the neck, injections of castor oil and turpentine were given, croton oil applied to the tongue, inhalations of ether were also used and ice placed on the head, but all proved ineffectual, for neither Dr Drysdale (who was consulted) nor I could do anything to prevent her death, which occurred just 24 hours after the birth of her babe

A post mortem examination was refused, but we believed that a rupture of a cerebral vessel must have taken place, for she was unconscious from the first fit

I was called by a physician to see a woman who had a convulsion whilst in labor As the head of the child was pressing on the perineum I assisted the delivery with my hands, which was soon followed by the expulsion of the placenta, and several clots of blood Another convulsion occurred, but by applying cloths wrung out of hot water, to the vulva, a free discharge took place Ice water was put on the head Her pulse was not full, yet she was unconscious, and had been so for several hours She was cupped on the nucha and temples, and an injection of oil and turpentine given On the next morning the doctor found his patient not only conscious, but in her right mind Her recovery was perfect in a few days

E B had an attack of eclampsia at 2 A M, was bled copiously, also cupped on the temples and behind the ears, became conscious and slept until daylight Labor began at 9 A M, and a dead babe was born at 10 30 A M No more fits, was soon well

S H, aged 35 years, pregnant with her fourth child, was very fat and full blooded, complained of headache and a "peculiar sensation extending from spinal column to the back of the head" Three pints of blood were taken from the arms, and a sinapism placed along the spine Labor began, but the os dilated very slowly, and when the expulsive pains set in she again had headache, and whilst the child's head was passing through the inferior strait she was seized with eclampsia The bandage was loosened and the vein reopened at the arm Another fit occurred as the head was coming through the soft parts, but it ceased when the dead child was born She remained unconscious for about an hour and then inquired for her babe, but was not told of its death This apparent improvement was of short duration, for more convulsions followed, when a cupper was sent for, and the assistance of my friend, Dr Stewart, who came promptly Cups were applied to the nucha and down the spine Inhalations of ether were used and her bowels were opened by injections of oil and turpentine, yet the fits continued Twenty grains of bromide of potassium were given by the mouth—for at times she could swallow Her pulse was 112, but compressible, the temperature 104°, the breathing labored The urine drawn by a catheter was full of albumen

Four hours later the pulse was 130, temperature 104½, breathing heavy, stupor increasing A blister was put on the back of the neck, warm cloths were applied to the pubes to increase the lochial discharge,

which was scant, but all our efforts were useless, for the stupor and convulsions were soon followed by coma and death No autopsy was permitted

C I, aged 24 years, being in the seventh month of utero-gestation, was œdematous over the whole body, and had severe headache, for which she took bromide of potash and diuretics, which relieved her considerably On January 16 she was seized with convulsions and became unconscious about midnight, when a neighboring physician was called in, who attempted to bleed her, but was unsuccessful The convulsions occurred every few minutes, she would turn her head to the left side and bite her tongue, so that bloody froth was issuing from her mouth Her pulse was full and hard, her breathing stertorous, and her face congested at times She had been in this condition about two hours when I arrived A leecher had been sent for, who applied leeches to both temples and the nucha, from which the blood flowed freely Cold water cloths were placed on the head and warmth to the feet Ether was given by inhalation, which controlled the fits somewhat, but several hours elapsed before they ceased and she became conscious During all this time the os uteri was firmly contracted, and showed no signs of labor

She was affected with dimness of vision for several days after, but under the use of diuretics and bromide of potash the dropsical effusion gradually subsided from her limbs and body, and by the help of quinine, iron, and generous diet she soon recovered, and resumed her household duties Labor, however, did not occur until February 8, when "the waters broke," and a putrid fœtus was expelled from the uterus without any trouble, which was soon followed by the placenta

H Y, a primipara, of nervous temperament, was suddenly seized with eclampsia at the beginning of her labor Her pulse was compressible and her face pallid, the jerking of the limbs and the twitching of the muscles of the face, with the turning of the head to one side, occurred frequently There was no stertorous breathing, but she was unconscious

An injection of ʒj hydrate of chloral in ʒiv of water immediately arrested the convulsions and she became quiet An examination per vaginam showed the os dilatable, and a face presentation, which was changed to an occiput anterior of the vertex, but during my manipulation she became restless, and I was obliged to repeat the chloral Feeling the necessity of a speedy delivery, and as the os was well dilated, I applied the forceps and brought the child's head through the bony pelvis quite easily, the body was born naturally without any help, and the placenta soon followed, but the child was dead The mother was still unconscious, but being put comfortably in bed, rested quietly There was no return of the convulsions She was not aware of what had occurred until 24 hours had elapsed, when, feeling sore, she inquired of the nurse what had happened whilst she was asleep Her recovery was rapid This was an asthenic case, and relieved without depletion

On considering the symptoms of eclampsia, and the conditions of the patients, the majority of obstetricians have concluded that depletion, either general or local, is the best treatment, followed by purgatives and opiates, with inhalations of ether and injections of chloral, that speedy delivery will often stop the convulsions Post-mortem examinations have revealed nothing positive as to the cause or pathology of eclampsia.

TREATMENT OF CHRONIC SUPPURATIVE OTITIS MEDIA

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY SETH S BISHOP, M D,
OF CHICAGO

The object of this paper is two fold *First*, to elicit a discussion of the subject which shall set forth the latest and best methods of treatment, *Second*, to protest against a mode of treatment that has been highly lauded of late I refer to what is called the dry treatment, in which the external meatus is filled and even packed, with a powder that is to remain from one visit to another Although the principle involved did not recommend the practice as being in accord with good surgical doctrine, the favorable results reported induced me to try it, as I have a habit of trying all new methods which promise any improvement on the old

The plan proposed was to remove all the pus from the drum-head and meatus with dry absorbent cotton, inflate the middle ear, again remove what discharge was forced through the perforation of the membrana tympani by the inflation, and then blow powder into the middle ear, and fill the external meatus with the same It was even urged that the powder should be put in, a little at a time, and each layer packed, one upon the other, until the meatus was full It was claimed that in this way the discharge was speedily stopped, and it was—that is, the exit was stopped as is a bottle with a stopper, so that the contents could not escape But suppose you want the contents of the bottle to escape as you probably do, how is this to happen unless you tap it at the bottom, as one does in the nasal douche? This is just the condition presented by an ear tamponed in this so called dry method The discharge can hardly escape through the solid packing of powder which the absorption of moisture converts into a dense plug The purulent discharge does not dissolve it even if a soluble powder is employed, and when iodoform or bismuth is used solution is clearly out of the question What results? The formation of pus does not often cease at once It fills the middle ear and finds exit through the Eustachian tube, if the tumefaction is not too great When the tube is not patulous the damming up of the sewerage of the tympanum will naturally force the pus through the mastoid antrum into the cells, after the middle ear has filled A very serious aggravation of all the symptoms is likely to follow

That this method is contrary to a very important prin

ciple of surgery must be patent to all An abscess should not only be opened, but should be kept open until the pyogenic process ceases It is a fallacious doctrine that air can or should be excluded from the middle ear in this manner Air will gain access to this cavity through the Eustachian tube and furnish pathogenic germs Free drainage should be maintained through the canal built by Nature, in order to avoid a complication of the existing trouble with mastoid disease Moreover, it is problematical whether one ever thoroughly cleanses the middle ear of pus by this dry method, even if the perforation be an unusually large one The cotton is not likely to enter the tympanic cavity and it is not desirable to have it for there would be danger of entangling the ossicles in its meshes and dislocating or removing them

The most rational and successful treatment I have tried is the following Cleansing the external meatus and middle ear thoroughly with injections of a 1 10,000 solution of mercuric bichloride, inflation by the Politzer method, or catheterization, iodine vapor if stimulation is required, drying the part with absorbent cotton and dusting them with finely pulverized boracic acid containing ½ of 1 per cent of mercuric bichloride, or if this should cause any unpleasant sensation, iodoform or boracic acid may be substituted

Hydrogen peroxide is valuable for cleansing the ear when there is a large amount of debris present in the form of pus mixed with epithelial scales, or cheesy concretions In addition to its excellent mechanical effect due to effervescence, the oxygen liberated destroys bacteria The latter result is also effected by the sublimate solution which in one half the strength mentioned will destroy bacteria in ten minutes The inflation ought to expel the fluid contents of the middle ear In cases of brief duration iodine is not required, but in very old cases, when the vital forces seem to have lost their powers of recuperation and resistance to pathogenic germs, tissue changes—the process of absorption and nutrition—may be favorably influenced by the judicious use of iodine vapor Drying the parts before dusting them with the powder leaves the patient more comfortable than the chilling effect of evaporation does The powder when slightly wet becomes hard and produces a feeling of stiffness, and sometimes of soreness Then if the powder be left dry we are enabled to determine at once when the discharge ceases

It is not necessary to fill the ear with powder If enough be insufflated to barely cover the suppurating membrane, all is accomplished that can be expected from the remedy, and the functions of the ear are not materially interfered with—an important consideration with many patients This treatment leaves no obstruction to free drainage, and in no manner invites mastoid trouble When the disease has just passed from the acute to the chronic stage the boracic acid powder had better be used without the bichloride, for the latter may cause some disagreeable crackling sensations and even pain But in the strength mentioned it is not likely to do so unless there is considerable inflammation

At the meeting of the Illinois State Medical Society, held in this city three weeks ago, the efficacy of iodoform as an antiseptic was called in question While the experiments of Heyn and Roysing, of Copenhagen, show that iodoform is inert in the presence of bacteria while the remedy remains in a dry state, de Ruyter has proved that iodoform in the presence of the fluids of suppurating surfaces undergoes chemical decomposition during which new iodine compounds are formed The splitting up of the iodoform, its partial solution and absorption, resulted in the destruction of the ptomaines, the product of pathogenic micro organisms, and hence the arrest of pathologic metamorphosis The laboratory thus confirms the practical conclusions which years of experience have forced upon the profession In conclusion, let me add in support of the method here outlined, that no routine treatment has ever yielded the uniformly satisfactory results in my hands that this has Were there time to enter into more minute details it would be interesting to consider the variations of treatment required by necrosis, etc , but that would extend beyond the scope of this paper Numerous illustrative cases might be adduced from my records, but I will mention but one that I have now under observation, in which the hearing was nil from chronic non suppurative inflammation of the left middle ear, and the voice could be heard only by shouting in the right ear, in which chronic suppurative inflammation had existed for over forty nine years I removed from both nostrils large polypi, which had prevented nasal respiration for twelve years The treatment I have described stopped the discharge in four days, and subsequent catheterization, etc , restored some hearing in the left ear, and so improved the right as to render conversation audible at a distance of fifteen inches

719 West Adams Street

RESECTION OF THE INTESTINE FOR FÆCAL FISTULA

Read before the Chicago Medical Society, October 3, 1887.

BY F HENROTIN, M D ,
OF CHICAGO, ILL

About five weeks ago I was called to Pullman, in this State, to see a patient On my arrival I found the patient affected with fæcal fistula The history of the case was this The woman had been affected with an obstruction of the bowels about fifteen days before I saw her The obstruction was evidently in the left inguinal region, as a mass was found there, which the physician in charge tried to reduce Failing in reducing it, she called in consultation a physician from Chicago, who went out there, and by dint of manipulation they succeeded in reducing this hernia Immediately succeeding the reduction of the mass in the groin, the patient complained of a great deal of pain, and a truss was fitted over the place where the hernia had existed This truss being somewhat tight gave rise to a great deal of pain, and after two or three attempts at periodical times to wear the truss it was laid aside The parts

by this time were considerably swollen and required attention In four or five days an abscess over the part had formed The pus was evacuated, and within forty eight hours there was seen a liquid substance oozing from the wound, and this developed into a well marked fæcal fistula (I should say that this was a femoral hernia on the left side) The fistulous opening was, at the time I saw the patient, very large and at the outer part would easily admit the thumb On examination I found the woman very much emaciated, thin and extremely weak She had then had this fistulous opening running about eight days, the parts around the opening were excoriated and the edges of the wound were in a gangrenous condition The discharge from it was excessive, and consisted of a greenish fluid exuding in large quantities, and mixed with this was a yellowish emulsive substance, having a slight fæcal odor

The weakness of the patient and her general condition, as well as the appearance of the wound, made me decide upon an operation Having given the matter careful consideration I operated the second day following There was no opportunity to do the operation under antiseptic precautions The surroundings were not the best for such an operation, but as far as it lay in my power antiseptic precautions were thoroughly carried out The instruments were all very carefully gone over beforehand, and the sponges and all material used was thoroughly and carefully prepared I decided upon simply making an incision in the linea alba of the lower abdomen, and taking out and detaching the bowel

I made an incision about three and one-half inches in length so as to get sufficient room, and entering the abdomen I slipped a large sponge into the opening, so that the end was immediately beneath the attachment of the bowel at the opening, I also packed in two or three little sponges at the side of this long sponge, in order to protect the parts as much as possible The large sponge reached from a little below the fistulous opening to the opening in the abdomen, so as to cover the parts thoroughly I then detached the ring of the intestine by slipping a finger around it and gradually working it apart, and so was able to grasp the intestine and bring it to the surface To make sure that the intestine did not slip, I had introduced a female catheter through the external opening four or five inches into the bowel, so as to be perfectly certain of bringing the parts to the opening without delay Everything worked very satisfactorily, and the bowel was brought to the surface, and outside upon the abdomen in a very few moments The only part in which there was any difficulty was in detaching the bowel from the opening Never having tried the procedure before, I was surprised at the amount of force necessary to detach it When I brought the bowel to the surface I packed sponges around it, and held the edges of the wound together in such a way that I knew that there was no possibility of further infection during the fixing up of the bowel Much to my chagrin, when I had brought the bowel to the surface, I found there was a very large and jagged opening in the bowel, and that the efforts at detachment had served it almost down to the mesentery

There apparently remained nothing to do but to take away the part, resect the intestine entirely, which I immediately did Taking the bowel up carefully (with these prepuce forceps) on each side, about three-fourths of an inch beyond the furthest point of the tear, I cut the bowel off square on the side of the tear, leaving one fourth of an inch margin These forceps answered the purpose admirably, each blade being covered with a soft rubber so as to leave no impression on the bowel I took them off once or twice during the process of stitching, and found there was not too much pressure being used, not enough to wound or injure the bowel Having cut off the bowel down to the mesentery I thought it best not to injure the mesentery, which proved, I think, a great element in the success of the case, and which has been further proved to my own satisfaction to be the proper way of procedure When I reached the mesentery I simply cut right straight across along the edge of the mesentery, and left it as nearly whole as I could, cutting directly in a line between the bowel and mesentery I then stitched up the intestine After stitching up the bowel and fixing up the mesentery to my satisfaction, I returned the bowel to the abdominal cavity, and looked for any debris or blood, but not finding any stitched up the abdominal wall tightly I had the long narrow sponge left from one opening to the other, and apparently not a drop of oozing had taken place in the abdomen I replaced this long sponge with a flatter one before stitching the abdomen, so as to protect it from any bleeding stitch holes, and in a short time had the wound closed, and had the satisfaction of knowing that there was no blood in the abdominal cavity

As regards the original opening, I simply scraped it off under Poupart's ligament, refreshed it, and introduced through that opening my drainage tube, closing the central wound entirely I also introduced a second tube into a sinus that went up along Poupart's ligament, along the inguinal canal

The case did remarkably well At no time was there any temperature beyond a few fractions of a degree above 100 She never even vomited There was no tympanitis, no bad symptom whatever The patient is now, after several weeks, doing quite well She was 59 years old and extremely delicate, but she is apparently very nearly in her normal health except that she has some colicky pains and occasionally a loose stool, whether this is due to a stricture and may prove permanent in character, I cannot say

The after treatment needs no consideration The dressing put on was merely the ordinary dressing of laparotomy after an ovariotomy—dry iodoform, an antiseptic cotton pad and antiseptic gauze outside The dressings were only disturbed once every four or five days There was a little abscess in the abdominal wall, but it gave no trouble and healed in a few days

The particular point I wish to bring to your attention is the propriety of operation The first item

of importance, which was very evident, was the extreme debility of the patient She was naturally a very weak woman, was 59 years of age, and whatever was to be done had evidently to be done soon Physicians who had seen the case and who assisted me at the operation, were also of that opinion, and they were possibly better able to judge than I was as they had watched the case from the first The patient was evidently failing, the pulse and general appearance indicated a great deal of weakness, and in addition was this constant drain I cannot tell the amount because I did not see the patient long enough, but it was considerable, the cloths and cotton padding, and dressings that were put on had to be changed several times a day, and when the abdomen was pressed above the wound this greenish fluid bubbled up in large quantities, mixed with a yellowish substance which I considered to be chyme, or rather chyle What else was to be done? Of course we know that in a fistulous opening of that kind it is an ordinary thing to make a plastic operation of some kind, but in this woman such an operation would have failed on account of the amount of fluid and the character of the opening, its edges being gangrenous, a pulpy greenish yellow The only way in which that patient could have been kept alive would have been to have given her food by the mouth, and tried to find the lower opening, injecting food in that portion of the bowel, and it would have been very hard to tell which was the lower opening The anatomy of the abdominal organs is such that we cannot always tell whether we are going up or down, under such circumstances But this case had to be taken care of, and something done at once The character of the fluid denoted that the opening was extremely high up, there was no dark substance, nothing that would represent fæcal matter, no appearance to indicate that it was low down, and the constant drain and the amount of fluid indicated that it was high up, because we know the villi of the intestines and lacteals take up the fluid as it goes along, and the lower down we get into the bowel the more the fluid disappears For these various reasons it seemed to me that the one thing to do was an immediate operation, that in view of the weakness of the patient, the character of the fluid and the evident high situation of the fistula, any other procedure would be followed by failure

The reason of the resection of the bowel is evident to you all, on viewing the specimen It certainly would not be very good policy to try and patch up a bowel torn up in that way As regards the way in which the operation and the stitching of the bowel was done and the way in which the mesentery was treated In taking the bowel out I found that the serous coat was extremely soft and pulpy, and I soon found, on trying to put a stitch through, that the least little pull would tear through the serous coat, and I really believe that a large portion of cases of resection of the bowel, where the stitches are taken as much as possible in the serous membrane, are very liable to fail on that account The way I stitched up the bowel was this I put one row of stitches made of silk in the whole thickness of the bowel, the three coats I started in on the edge on one side and then came out so as to bring my free ends on the inside of the bowel I then tied This was a very easy matter when the two portions of the bowel were held up by the forceps, and after thorough cleansing the two parallel edges were sewed together, each stitch being put so that it would fall inside when the bowel was brought around. The stitches were placed a little over a sixth of an inch apart, and I had no difficulty in going around the bowel in that way, always going through each of the three coats When I got down to the last two stitches I began on the outside and brought the needle through what was left of the unsutured inside of the bowel, then started another needle through the same way and brought them both out and tied The last stitch I put in the same way, bringing out the needles from each side through a little crevice and tied as close as I could, and then it was easy to take the knot and insinuate it between the edges of the last two stitches, so that it was tied on the inside I then put in a suture of *continuous* catgut stitched on the outside serous coat only After each stitch I had my assistant draw the catgut snug to hold the ground I had gone over, and so managed to surround the whole bowel without difficulty

As regards the mesentery, I did not interfere with it, but treated it in this way Here we have a section, this being the bowel above and this the mesentery below When I got down to this I stitched my mesentery in this way, not going through to this side so as to interfere with the circulation in this direction, and to make a V and hold it together in this way You can see the absolute security which it gives All authorities agree that interference with the mesentery is what produces the liability to sloughs, and they are extremely careful to tell us to interfere with the mesentery the least we can Another good reason for this treatment is that when the parts are brought together and the mesentery is not held its movements produce a strain on these two or three lower stitches and cause them to cut through, and at the same time allow fluids to pass out and produce fatal results So I stitched the mesentery in order not to destroy any of it, and at the same time hold it together so as to make the parts perfectly firm as a support to the bowel

Another item that may or may not prove of importance was this In cutting the bowel down on each side, having my clamp on, just before reaching the mesentery I curved my section slightly toward the side of the wound on both sides It seems to me this is of value, as this is apt to be a weak spot There being an accumulated amount of tissue here you can with this thickness of tissue take in a stitch on either side and hold them firmly so as to prevent as far as possible any strain at that place The larger the amount of tissue the firmer the union will be

One great factor toward the favorable issue of the case was that the woman hardly stirred, and did not vomit throughout the whole operation, and that the bowels at the time were almost absolutely flat That has a great deal to do with the success of such cases

It is a question whether in a certain proportion of

cases of hernia of a certain variety it would not be better to operate in this way About a week ago I was called to see a patient in Lake View who was vomiting and had evident obstruction of the bowels On examining the patient I found a bunch of something peculiar in the groin in the inguinal canal on the right side It was evidently something coming from the inside of the abdomen, but I could not make out what it was It did not have the appearance of bowel and I was loth to manipulate it very much Yet the anatomical relations were such that it evidently came from there I tried in every way to reduce it, but without success I was so certain that it was not the bowel but was omentum that I allowed 48 hours to go by in order to watch the symptoms At the end of 48 hours, and after various attempts at reduction, on Thursday I cut down on it and found, coming out of a very small opening, a piece of strangulated omentum The condition of the patient was such that it was with great difficulty that we could stay in the room and operate on account of the stench from his vomiting He lived a great distance from my home, and possibly I did not operate early enough During the night the patient had a free stool, the first he had had for a week, the stercoraceous vomiting stopped, and for 48 hours he did well The patient is alive yet and has a fair show, but the vomiting has recommenced and he does not look very well

Now, how much of the omentum is injured? I cut off the omentum as close as I could, pulled it out as far as I could before it was cut and tied it at the internal ring, and after tying it carefully with catgut I cut it off and put back the stump How much of that omentum is gangrenous behind that ligation? Of course the condition of the patient may be due to something else I introduced the finger right into the abdominal cavity, and there is no greater danger in making the incision in the middle line and stretching the opening from the inside carefully with the finger and pulling out the omentum to see what you are doing Our President told me that he once tied and cut off an omentum in an umbilical hernia The patient died and the post-mortem examination showed this omentum stretched and twisted around and strangulating the intestines, and of course the patient was not relieved by the operation The two cases taken together suggest the propriety in some cases of hernia that have stood for a long time, that were originally acute cases and probably omental, but where, from the length of time the hernia had existed, there was reason to suppose that there was considerable injury to the bowel or omentum, as to whether it would not be the best thing in these cases to open the abdomen carefully in the middle line, because you can reach down in the groin and, after stretching the internal and if necessary the external ring, bring out the strangulated parts and see plainly what is necessary to do

On examination of the specimen before you one thing is plainly discernible I was not mistaken as to the locality of the injury There are no certain ways of always knowing the exact portion of the bowel affected The lower part of the duodenum does not differ particularly from the upper part of the jejunum, but we know that the higher up we are the greater is the amount of folds of rugæ so called valvular conniventes that are around the bowel When I operated on this bowel it was nothing but a mass of corrugated folds on its mucous aspect, and though this specimen has been more or less changed in appearance by being immersed in diluted alcohol, you can see all along on the inner side the rugæ that are still present, showing about the only way that I know of to distinguish the upper part of the small intestine Of course the anatomical relations of the bowel differ in different persons However, from its appearance and location, I suspect that this specimen is a portion of the jejunum

---

ARTIFICIAL RIPENING OF CATARACTS

Read before the Chicago Society of Ophthalmology and Otology

BY BOERNE BETTMAN, M D,
OF CHICAGO

This is a subject which has not received the recognition from fellow-colleagues that its importance deserves Only a few articles and comments, scattered here and there, can be found relating to the relief of persons having non mature cataracts The third number, Vol xl, of *Knapp's Archives*, contains a communication from the able pen of Prof Forster, of Breslau, entitled "On the Maturity of Cataract" Forster calls attention to the annoyances patients are subjected to who are afflicted with cataracts of slow development In many persons the process of degeneration extends over a period of months and years, leaving them in a helpless condition, and in many instances obliging them to forego the enjoyments of life and resign life supporting and profitable positions

So long as the cararact is not mature, an operation is contraindicated So long as the cortical substance is still firmly adherent to the capsule, extraction of the lens cannot be performed with perfect safety to the patient, for, as Forster correctly states, the remaining layers of cortical substance will imbibe aqueous humor, swell, and give rise to iritis and other dangerous complications In order to produce more rapid degeneration of the lens substance, he proposes trituration of the cortex The procedure consists of gently rubbing the cornea with the blunt end of an instrument, usually a strabismus hook or iridectomy forceps The pressure exerted upon the cornea is transmitted to the lens, loosening and splitting the still adherent and semi opaque cortical lens fibres These, in the course of days and weeks, become perfectly opaque The object of the operation has been accomplished, the cataract is mature I was very much impressed by Prof Forster's article, and resolved to try his method whenever occasion permitted I have used the expedient quite often, but have modified it to suit my individual tastes Instead of rubbing the cornea, I bring the pressure to bear directly upon the lens, by pressing against the capsule with a spatula, usually employed

to replace prolapsed iris I prefer this method to the one recommended by Forster for the following reason Trituration of the lens always follows an iridectomy After the escape of aqueous humor iris and lens move up against the cornea, the iris contracts and the pupillary field becomes small When the blunt instrument now is rubbed against the cornea the pressure, unless limited to the small pupillary area, will not only break down the lens fibres, but will subject cornea and the delicate iris tissue to an unnecessary irritation I therefore, as before mentioned, carefully pass the spatula into the anterior chamber, and if necessary behind the iris, and gently stroke and press the lens in any direction

Great care must be observed not to exert too much pressure, otherwise a dislocation of the lens might ensue The flat side of the instrument should always be held against the lens surface If tilted so as to bring the edge to bear upon the capsule, it no doubt would rupture the latter It is unnecessary to add that the strictest antiseptic precautions are religiously adhered to, and that the eye should be fixed in case the patient shows an unruly disposition This, however, is rarely necessary, owing to the anæsthetic effects of cocaine The distribution of opaque lens fibres and general breaking up of the cortex can readily be seen with the naked eye during the operation The mother of pearl sectors split, break into pieces, and are forced from their former positions In the course of a few days, yea, even after twelve hours, the entire appearance of the lens has changed Its anterior surface has now a uniform mottled appearance When illuminated it frequently resembles a bag entirely filled with a granular mass In successful cases it becomes entirely opaque, cutting off the yellowish reflex from the nucleus

This delicate manipulation has rendered me great service, and has rescued many of my patients from a condition which, to say the least, was unpleasant

The results of trituration of the lens are usually very marked, and in some cases may be termed instantaneous Vision equal to from $\frac{3}{200}$ to $\frac{4}{200}$, *i e*, counting fingers at from three to four feet, can be reduced to qualitative perception of light in twelve hours In the majority of cases, in fact in every instance where the trituration has been thoroughly accomplished, the lens can be extracted in from three to six weeks after the preliminary operation During the removal of the opaque lens, the cortical matter escapes as a semi fluid, flocculent mass The pupillary field is easily cleared of cortical remnants, and the danger attributed to the lodgement of transparent particles of lens substance in the wound or on the iris, is entirely overcome

A few examples may suffice as illustrations

Case 1—January, 1883 Mrs S, æt 60 Left eye, nuclear cataract Mother of pearl sectors in cortex Amber colored nucleus Slight reddish reflex from fundus Counts fingers at five feet Right eye, incipient cataract, fingers at ten feet

June, 1883 Condition not materially changed Sight in left eye has decreased, fingers at eight feet Left eye vision perhaps a trifle less than in January The patient being very anxious for an operation, I proposed preliminary iridectomy and trituration of cortex She readily consented Operated June 5 June 25 I lens, to all appearances, perfectly mature July 15 extracted the lens Recovery rapid and uncomplicated V = $\frac{20}{30}$

Case 2—Sept, 1886 Mr H, contractor, æt 62 Immature cataract, both eyes Unable to walk about, since two years, without attendant Vision, both eyes, counts fingers at four feet Nuclear cataract Reflex from fundus dull red

Oct, 1886 Iridectomy and trituration of cortex, right eye Six days later cannot count fingers, only able to discern movements of hand I extracted the lens three weeks after the first operation The lens and cortex were easily removed On the fourth day I found my patient out of bed playing cards He left the hospital two days later with vision equal to $\frac{20}{30}$

Case 3—Under observation three years Immature nuclear cataract, both eyes After much persuasion he yielded to my frequent demands and permitted me to mature the right lens Vision before operation, counts fingers at a distance of three feet Twelve hours later nucleus no longer visible, covered by a layer of white opaque cortex No iris shadow Removal of lens and subsequent recovery, with good vision, after a lapse of three weeks

The conclusions arrived at in this paper are as follows The operation is a feasible one It is easily executed There is no danger accompanying it Its results are always marked and rapid The subsequent removal of the lens is made more facile, and danger from secondary complications after extractions are greatly lessened

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS —In regard to tuberculosis of bones and joints (see preceding numbers of THE JOURNAL) Volkmann goes on to say

27 Wounds from operations on joints and bones often become tuberculous before perfect healing is accomplished, fistulas and drainage openings fill with fungous granulations, parts of the wound already healed re open, and new tuberculous abscesses form In such cases very energetic treatment is to be recommended, renewed scraping out, cauterization with the thermo cautery, wide incisions, and particularly tamponning of the open, perfectly cleansed wound with antiseptic gauze (particularly iodoform and sublimate gauze) The last measure is probably the most effective, and in the most severe cases should not infrequently be put in practice immediately after the first operation But I do not consider it advisable to carry the principle of open treatment of wounds too far, since we often get primary union after these operations

The main thing, however, is not to wait too long for the second operation in tuberculous recurrences, in order to prevent the disease gaining too much

ground, and to interfere immediately when a new relapse appears It is often necessary to make as many as 4 or 6 operations, and more, at intervals of a few weeks, always narrowing and circumscribing the diseased area, in order to get a perfect and permanent cure

28 It seems that the operation for joint, and particularly for bone tuberculosis, in consequence of the entrance of tuberculous virus into the opened blood vessels, sometimes gives rise to the development of an acute miliary general tuberculosis (most frequently running its course with basilar meningitis)

29 It has been a well known fact, since the clinical types formerly known as tumor albus, atheroma, Pott's disease, spina ventosa, etc , were first recognized, that these affections even in the graver cases have often terminated in spontaneous recovery, and that the affected persons have reached advanced age, notwithstanding the more or less impaired mobility and function of the affected limbs, the cicatrices of which show the gravity and extent of this process As all these disturbances represent only varieties of tuberculosis of bones and joints, it is entirely useless to discuss the possibility of their spontoneous recovery

30 *Tuberculosis of tendon sheaths* appears partly as diffuse fungous affections of the sheaths, partly as solitary knots (isolated tubercles) Since the tendon-sheaths are generally situated close to the joints, it is necessary to warn against confounding this affection, when a fistulous opening is established, with caries of the joint or affections of the bone The treatment consists in cutting away the diseased sheath, scraping out, etc

31 *Tuberculosis of Lymph Glands* —In all the tuberculous affections thus far mentioned, the lymph glands that derive their supply from the diseased region may be infected, and become tuberculous This affection, earlier called scrofulous inflammation or cheesy degeneration, is a genuine tuberculosis The susceptibility of the lymphatic glands of the different regions of the body to the tubercular virus, is, however, very different The glands of the neck are by far the most frequently affected, and then those of the elbow, less frequently affected are those of the axilla, and most rarely those of the popliteal space and of the groin It is a rare exception that tuberculosis of the inguinal glands is found, even in the gravest tuberculous affections of the bones and joints of the foot

32 Very frequently, however, do simple hyperplastic, irritative and inflammatory swellings of the glands, such as accompany inflammatory and catarrhal processes of the skin and mucous membranes (and known as sympathetic or cosensual), later becomes tuberculous, when a certain constitutional disposition (scrofulosis) and hereditary infection is present The glands do not subside when the affection that caused them to swell disappears, they become larger, caseate and soften, and examination after extirpation shows a true miliary and bacillary tuberculosis This process, scrofulosis of the lymph glands, is most frequently noticed after primary affections that themselves are regarded as scrofulous, as, for example, in the case of glandular swellings after skin eruptions, chronic catarrhs, blenorrhœas, etc

33 How far cheesy deposits not belonging to tuberculosis (not bacillary) may exist in the lymph glands is not yet decided with sufficient certainty

34 Tuberculous lymph glands are best removed with the knife, and where we have to do with glandular lumps (Lymphdrusenpakete), as is usually the case, these should be removed on the same principles as the affected axillary lymphatic glands in a case of carcinoma of the mamma Scraping out the soft tuberculous glands with the sharp spoon is insufficient, since there still remains the diseased capsule of the gland, at least, and generally also the swollen and infected but not yet soft lymph glands in the neighborhood, and they will cause a recurrence It is not always possible, however, to avoid the scraping out

35 How far arsenic used internally may be effective in tuberculous (scrofulous) swellings of lymph glands, can be decided only by further observations —*Langenbeck's Archiv*, Bd 33, Hft 1

MODE OF FIXATION OF THE SCAPULA AND FRACTURE OF THE CORACOID PROCESS —At the meeting of the Royal Medical and Chirurgical Society on November 8, MR ABURTHNOT LANE read a paper on this subject He showed that in extreme flexion of the shoulder joint the scapula undergoes a movement of rotation upon an axis whose general direction is obliquely inwards and forwards, and that this rotation is abruptly limited by the impact of the coracoid process upon the under surface of the clavicle He illustrated the manner in which the frequent performance of this movement under the influence of considerable strain determines in such laborers the development of a coraco clavicular articulation, the mechanism of which he had already described in the Guy's Hospital Reports, 1886 He then referred to the very great difficulty which is usually experienced in breaking down adhesions between the humerus or scapula, these adhesions being in most cases the result of inflammation The difficulty arose from the inability to fix the scapula He showed that the scapula can be firmly fixed by flexing the shoulder joint completely, the coracoid process and clavicle being held forcibly in apposition, and that when the scapula is so fixed against the clavicle the humerus can be rotated forcibly upon its own axis, and can be completely adducted and then abducted very considerably without the humerus being accompanied in its movements by the scapula In this manner all adhesions between the two bones can be readily broken down He then criticised the statements made by surgical writers that the coracoid process is always broken by direct violence, and referred to two cases quoted by the author of the article on "Fractures of the Upper Extremity," in Holmes' System, to prove the truth of the above assertion, which, he said, showed that the very reverse was true in this case, for the reason that when the shoulder-joint is completely flexed it is practically impossible to fracture the coracoid process by direct violence He also referred to the extreme inaccuracy of published statistics of the relative fre

quency of fractures of the several bones, and particularly of the coracoid process and acromion He had never found a single instance of fracture of the coracoid process in the dissecting room, but he had observed that fracture of the acromion occurred more frequently than fracture of any other bone in the body MR W ADAMS agreed with the anatomical and physiological conclusions of the author, but he could not concur with the surgical conclusions, for in an ankylosed joint it would not be possible for the joint to be flexed The difficulty of fixing the scapula was not great He had never found any difficulty himself in fixing the joint firmly There often appeared to be plenty of movement, but this was of the scapula, and not really in the joint In a few difficult cases the ankylosis could not be broken down, and he should recommend that such cases be left alone MR CLEMENT LUCAS said it was new to him that the coracoid process could be fractured in the way Mr Lane had described, and the explanation was very easy to understand He agreed that fracture of the acromion process was more frequent than was commonly supposed Attempts at flexion of the shoulder would inevitably bring the coracoid process into contact with the clavicle, and so afford the necessary *point d'appui* MR HOWARD MARSH thought the explanation of fracture of the coracoid as likely to be the true one He considered that the difficulties of fixing the shoulder joint were not so great as the author had inferred In breaking down adhesions the use of anæsthetics was most desirable If the joint be really fixed as determined under anæsthesia, he should advise that the case be left alone, for any temporary improvement was most likely to be followed by increased ankylosis and increase of the joint disease The acromion may be apparently detached by the chronic rheumatic joint disease MR LANE considered that the changes in the acromion were more frequently due to injury than to a rheumatic process —*Lancet*, Nov 12, 1887

CARBOLIC ACID IN TRACHOMA —Starting from the supposition that trachoma is caused by a specific microbe (as was first pointed out by Sattler, and later on supported by independent researches of Michel, of Wurzburg, and E E Schmidt, of St Petersburg, see the *London Medical Record*, April, 1887, p 166), DR J SHTCHEPKIN, of Krasnoufimsk, has attempted (*Vratch*, No 42, 1886, p 479) to destroy the pathogenic agent by means of injecting into the palpebral mucous membrane two or three drops of a 2 per cent solution of carbolic acid Seven successive cases of follicular trachoma were treated by him after that plan In all of them, after two or three injections (repeated at intervals from three to twenty-two days), a complete and radical cure was obtained, trachomatous grains, however large, tracelessly disappearing in the course of a few weeks Since the carbolic injection is painful, a 2 per cent solution of cocaine should be instilled into the eye about five or ten minutes before the operation Lachrymation and redness caused by the latter disappear spontaneously in ten or twenty minutes Shtchepkin's successful results induced Dr L P Serebrennikova, a lady doctor attached to the Permgubernskaia Zemskaia Infirmary, to try so simple a method in nine trachomatous cases of her own As may be gathered from her short communication in the *Vratch*, No 32, 1887, p 614, she is far from being prepared to support his statements Follicles disappeared in only one of her cases—in that of a recent trachoma in an ulcer of 24, where the carbolic injection had given rise to intense local inflammation Even in this case the successful result is attributed by the author to the inflammatory process, and not to a specific (antibacterial) action of the drug In the remaining cases, the injection produced a more or less considerable œdema and other inflammatory phenomena, which in two cases attacked also the cornea, and intensified already existing pannus After the reactive irritation had been allayed, the conjunctiva was found to be in an exactly identical morbid state as before the treatment Hence the author gave up any further experimenting in that direction It is just possible that such a striking difference between the result of the two authors might, at least partly, depend upon a difference in the procedures respectively adopted While Dr Shtchepkin lays great stress on injecting into the most superficial layers of the mucous membrane ["it is the most essential condition," he says, "therein the operator's whole skill consists"], Dr Serebrennikova seemingly always injected into the submucous cellular tissue —*British Medical Journal*, Nov 12, 1887

ANTIFEBRIN IN THE FEBRILE DISEASES OF CHILDREN —HIDOWITZ reports the use of antifebrin in fifty three cases, including four of scarlatina, eleven of measles, eleven of measles with subsequent pneumonia, two of measles with tuberculosis, two of facial erysipelas, four of croupous pneumonia, two of lobular pneumonia, two of pleuro pneumonia, four of bronchitis, three of tuberculosis, four of follicular tonsillitis, three of gastricismus, one of acute intestinal catarrh An interesting fact is that at the end of ten or twenty minutes after the medicine was taken the temperature began to decline, and continued steadily until it reached its lowest mark After remaining at this point for a short time it began to rise again The rapidity with which the temperature declined seemed to depend not so much upon the size of the dose as upon the peculiarity of the child and of the disease Another observation was the very favorable effect upon the general condition of the children Those who had previously been restless and fretful became quiet and soon fell asleep In several instances the severe symptoms connected with collapse were quickly relieved after the ingestion of the medicine Scarlatina and erysipelas were more rebellious to the antipyretic action of the drug than any of the other diseases in which it was used, the temperature falling only a few tenths of a degree In pneumonia occurring as a complication of measles, in croupous and lobular pneumonia, in measles complicated with tuberculous affections of the stomach and intestines, the antipyretic action of the drug was prompt and energetic The pulse be-

came fuller, its frequency being diminished, though not always in proportion to the decline of the temperature, the respiration became deeper and more quiet The drug was given in the form of powder, and in doses of 1½ grains to children three or four years of age To older children, 3 or 4½ or even 7½ grains were given Small doses usually sufficed for poorly nourished children, the reaction being much more energetic than in more robust children As much as 30 grains were given in the course of a day The antifebrin never produced any perceptible effect upon the duration of the disease In some cases of croupous pneumonia its use was accompanied by profuse perspiration, with cyanosis of the face and the ends of the fingers —*Archives of Pediatrics*, October, 1887

SUDDEN ŒDEMA OF THE GLOTTIS AS A FIRST SYMPTOM OF CIRRHOTIC KIDNEY —B FRAENKEL reported an interesting case of this kind before the Berlin Medical Society The patient was suddenly seized with dyspnœa, and when the author saw him he was sitting on a chair and complaining of the want of breath A laryngoscopic examination showed swelling of the epiglottis and of the arytæno-epiglottidean folds As the patient was stepping into the carriage to be taken to the clinic, where tracheotomy was to be performed, he dropped dead At the autopsy intense œdema of the epiglottis and the arytæno-epiglottidean folds was found There was very marked contraction of the left kidney The right kidney was enlarged and in a condition of parenchymatous swelling The immediate cause of death was œdema of the larynx caused by the condition of the kidneys There was absolutely no effusion in any other part of the body The patient had never shown during life signs of any disease of the larynx The whole duration of the disease was not more than an hour The patient must certainly have suffered with albuminuria for some time, as the urine removed after death was rich in albumen In the discussion that followed, A Baginsky remarked that such a condition was observed also in the acute nephritis following scarlatina De Bary, of Frankfort, had been the first to describe acute œdema of the glottis as a first symptom in scarlatina nephritis Since then a few cases of the kind had been recorded —*New York Medical Journal*, Nov 19, 1887

TREATMENT OF RUPTURED AND DIVIDED TENDONS —DR C H WILKIN presents a table of thirty-two hitherto unpublished cases, of which twenty-eight were treated by suture, with good results in twenty-two and benefit in all He considers the injury in two classes, simple and compound While in the former almost all authorities seem to agree that rest and position are sufficient, yet it would seem that a better result and certainly closer apposition could be obtained by the use of the suture, of the propriety of the suture in the compound variety, there can be no question The plan of treatment recommended, is first thorough cleansing of the part and irrigation of the sheath of the tendon with a 1–1000 bichloride solution—except when the knee-joint is involved, when it should be 1–5000—by means of a small English catheter with a syringe attached, cocaine anæsthesia, and the use of silk worm gut suture two sutures being necessary in the average tendon, one being carried transversely through the tendon and the other antero-posteriorly —*Annals of Surgery*, August, 1887

OIL OF TURPENTINE IN DITHTHERIA —ROSE, of Hamburg, has treated 58 cases, with a mortality of 5 per cent, as follows He gave oil of turpentine three times a day in teaspoonful doses, mixed with spirits of ether—℥iv of ether to 1 teaspoonful of oil of turpentine A teaspoonful of a 2 per cent solution of sodium salicylate was also given every two hours Externally an ice bag was used, and gargles of a 1 per cent warm solution of chlorate of potassium This treatment gave the following results

1 Rapid lessening of the pulse rate and of the temperature, 2 Rapid alleviation of the subjective symptoms, 3 Shortening of the duration of the illness, 4 No exacerbation of the local process after the first dose of turpentine, 5 Only once was there danger of suffocation, and tracheotomy was done

Rose thinks that pencilling the throat as done in private practice, is generally useless He uses great caution in pushing the turpentine in anæmic cases, and in patients with weak hearts, and excessive cardiac action, from any cause, was carefully treated The food given in his cases consisted of bouillon, old port wine and milk, and ice and aerated fruit juices were given to quench thirst The turpentine was discontinued when the patient was free from fever In ordinary cases doses of from 3 to 5 drachms were used, and no intoxication was seen In one case paralysis occurred, but the patient recovered under the use of chlorate of potassium —*Therapeutische Monatshefte*, October, 1887

PHYSIOLOGICAL ACTION OF OIL OF TURPENTINE —At the close of an article on this subject DR HOBERT AMORY HARE gives the following summary

1 The oil of turpentine in small doses, resembling those ordinarily given in practical medicine, produces an increase in the number of the cardiac beats due to a direct stimulant action on the heart

2 In larger doses it produces distinct slowing of the pulse, due to a stimulation of the pneumogastric or inhibitory centre

3 That its influence on the vaso motor system, if at all, is very slight, either with large or small doses

4 That poisonous doses (5 c c to 10 c c) (ℳ 80 to 160) produce death by cardiac failure when injected directly into the jugular vein

5 That the drug in small doses increases reflex action somewhat, but in large doses decreases it, the increase being due to a stimulation of the spinal cord, and the decrease due to depression of the sensory side of the cord and afferent nerves —*Medical News*, Nov 19, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM IN ADVANCE $5.00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

HEART PUNCTURE IN CHLOROFORM NARCOSIS

The last contribution to the subject of cardiocentesis, and the most complete, is a paper read by DR B A WATSON, of Jersey City, at the last meeting of the American Surgical Association. The paper is all the more valuable from its containing the details of sixty experiments made on dogs, forty of the animals being injured and twenty uninjured at the time of the experiments. The experiments were made for the purpose of determining the possibility of arousing the heart into action, after its action had been stopped by chloroform narcosis, by the introduction of a needle into the organ. It will be remembered that the operation of cardiocentesis was first proposed and performed by Dr B F Westbrook, of Brooklyn, in 1882, though previous to this time, the heart had several times been punctured unintentionally without bad results.

In all these experiments commercial chloroform was used. In the first 50 cases the chloroform was administered rapidly, and atmospheric air was, so far as possible, excluded from the animals, in the remaining 10 cases the chloroform was given slowly, and contained a large percentage of air, in the first 50 cases, then, there was a certain degree of asphyxia with the narcosis. In the last 20 cases artificial respiration was used with special care, the animals in these cases having suffered no traumatism. Of 47 cases in which the cessation of the heart's action and of respiration as the result of the narcosis was noted, in 44 the heart's action ceased before respiration, in 1 case the heart continued to pulsate one minute after respiration had ceased, in 1 case the heart pulsated for thirty seconds after the animal had ceased to breathe, and in 1 case respiration and cardiac action ceased at the same time. In 34 experiments chloroform was administered rapidly, and without the admixture of atmospheric air, the average continuation of respiration after the cessation of cardiac action was nearly forty one seconds, the maximum being two minutes and the minimum five seconds. In the 10 cases in which chloroform was administered cautiously, and with a free admixture of atmospheric air, there was not a single case in which the heart stopped before the animal ceased to breathe.

The punctures made in the 60 experiments were as follows: In the right ventricle, 38, left ventricle, 6, right auricle, 6, superior vena cava, 3, inferior vena cava, 2, apex of the heart, 2, not stated, 1. The resuscitations that followed these punctures were: right ventricle, 9, right auricle, 1. The first 40 experiments gave 4 recoveries, and the last 20 gave 6, but it is to be remembered that the first 30 dogs were suffering from traumatism, and that the experiments were made for the purpose of determining the *effects* of cardiocentesis, while the experiments in the last 20 cases, were made for the purpose of showing the efficiency of cardiocentesis, when used in these cases in connection with artificial respiration.

In regard to the effects of a puncture of the heart in chloroform narcosis, a study of the paper shows that of the 60 punctures in two only did the heart fail to respond, the puncture being made in one of these cases one minute and thirty five seconds after cessation of cardiac action, and the needle was so firmly held by the tissues through which it passed that it could not be swayed by the feeble pulsations of the heart, and in the second case the puncture was made four minutes after cessation of cardiac action, and one minute after cessation of respiration.

The report shows that needle puncture alone was sufficient to arouse the heart to action in 22 cases, the average time that had elapsed between the heart stop and the puncture being one minute and twenty seconds—the longest period being two minutes, the shortest one minute. In two of these cases the action excited continued, the other functions were reestablished, and the animals recovered.

A most important question is, Can the heart that has ceased to beat be excited to action by needle puncture? A careful reading of the details of the experiments will leave no doubt that in the 22 cases the hearts's action had really ceased, and that the puncture did not simply stir up to increased action a heart that had almost stopped. In almost all of

the experiments it was noted that cessation of the heart's action commonly occurred before cessation of respiration, but when the needle previously introduced into the heart this order was reversed

Should the puncture be carried into a cavity of the heart in order that blood may be abstracted? From the conditions found after death from chloroform narcosis "it may be rationally claimed that blood may be advantageously drawn from the right side of the heart in chloroform narcosis I am, likewise, fully assured that this procedure is not only theoretically correct, but also entirely practical and highly advantageous What more rational treatment can be adopted in cases of chloroform narcosis than the puncture of the heart and the abstraction of blood " In cases in which respiration and the heart's action have ceased the urgent indications are to restore these functions as soon as possible, and the indications are so urgent that a resort to measures that would not otherwise be justifiable may be said to be demanded The only deaths in Dr Watson's experiments that may be fairly charged to the puncture are those due to the puncture of the vena cava Punctures of the auricles were sometimes followed by considerable hæmorrhage into the pericardial sac, and such wounds are by no means free from danger "The punctures made into the ventricles are not attended by any hæmorrhage from the interior of the organ, but there are occasionally found a few drops of blood within the pericardial sac, which has been poured out from some wounded cardiac vein " Dr Watson draws the following conclusions in regard to cardicentesis in chloroform narcosis

1 Puncture of the heart, especially the right ventricle, stimulates muscular contractions and may be advantageously employed in the treatment of this morbid condition

2 The best results are obtained when abstraction of blood from the cavity of the ventricle is combined with the stimulating effects produced by the entrance of the aspirator needle

3 Puncture of the right ventricle is a safer and more efficient operative procedure than puncture of the right ventricle

SECTS AND SCHOOLS OF MEDICINE

The New York *Medical Times* (homœopathic) for November, 1887, says editorially

"The two greater so called schools in medicine seem to be failing entirely in their duties to each other and to the public! There has been and is now a regular system of boycott going on in both of them toward such of their associates as dare to have opinions respecting ethics at variance with what these schools choose to dogmatically lay down as guides in their relations with one another

"In practice the great majority of both these bodies are in substantial accord so far as the use of therapeutic means is concerned, that is to say, all assert their willingness to adopt that means which will best subserve the interests of their patients

"In the Old School class, many seem afraid to employ small doses, even when confident of their superiority, for fear of the homœopathic designation, and the homœopathic class fights shy of the large dose, even when absolutely called for, for fear that they may be termed allopaths! Both these sects are thus doing themselves and the public an injury, and all on account of the sectarian designation

"How much better it would be for both of these parties to come out honestly and squarely and admit that there are occasions when small doses would be best, and that there are other instances when the larger, even the largest, may be required, depending entirely upon the effects to be obtained, and the mode of selection will be easily admitted, as it will be determined also by the end desired The Old School undoubtedly occupies the higher relative plane in the controversy by being free from sectarian designation, but still as a body it has a great responsibility at this juncture, and one that it should not shirk nor attempt to temporize with

"It is highly improper to use the expression 'practicing both ways,' and if there were no sectarian designation there would be no opportunity to make such a statement!"

Exactly so! And if there were no parties arrogating to themselves a "sectarian designation" or attempting to delude the people into the belief in "Old Schools" and "New Schools," there would be no occasion for any "system of boycott" And if the editor of the *Medical Times* is correct in saying that "in practice the great majority of both these bodies (regular profession and the homœopathic) are in substantial accord so far as the use of therapeutic means is concerned," why continue to use a "sectarian designation" for either? He justly concedes the fact that what he calls the "Old School" is "free from a sectarian designation," and as that embraces eight tenths of all the practitioners of medicine in this country, why do not the remaining two-tenths abandon their antiquated pretensions concerning special designations and special schools, and be content with the fair title of Doctor of Medicine? The matter is entirely in their own hands They selected their own exclusive "sectarian designations," and they can abandon them whenever they please But so long as any number of medical men choose to designate themselves by a "sectarian" name as a *trade mark* for the public, they should not complain if all other medical men leave them entirely alone, so long as they adhere to such exclusive trade mark

YELLOW FEVER —Reports from Tampa, Florida, to November 23, state that during the preceding two days there had been 5 new cases of yellow fever and 1 death, although the temperature had been below the freezing point On the 24th no new cases and no deaths, and the nurses from Savannah and part of those from Key West had been sent home The whole number of cases reported during the progress of the epidemic is 380 and 71 deaths

APPOINTMENT —The Chair of Surgery in the Rush Medical College, made vacant by the recent death of Professor Moses Gunn, has been filled by the appointment of C T Parkes, M D , already well known as the Professor of Anatomy in the same College

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Special Meeting, September 17, 1887

THE PRESIDENT, THOMAS M DRYSDALE, M D , IN THE CHAIR

DR GEO GRANVILLE BANTOCK, F R C S EDIN , London, England, made some

REMARKS ON THE REMOVAL OF UTERINE FIBROIDS BY ABDOMINAL SECTION

He said that the tumor that formed the text for his remarks had been removed the day before, from a single woman æt 36, a patient of Dr Joseph Price, and weiged between 5 and 6 pounds At first sight he had doubted the propriety of operating, because there seemed to be no indication for interference beyond the rate of growth of the tumor, and because the patient, as he had been assured by Dr Price, very much minimized the extent of her sufferings The matter was thoroughly explained to her, the danger of the operation was made clear, and it was pointed out that if operation were necessary at some time, she would never be in a more favorable condition for it The patient was aided by her mother in coming to a decision, and he was struck by the readiness with which they both decided in the affirmative This was so far fortunate, for it would be seen that the tumor had in its upper part already undergone cystiform degeneration (here an incision was made into the cyst before the Society, giving exit to over half a pint of a thin sero sanguinolent fluid) He was happy to say that the condition of the patient was most satisfactory

Dr Bantock then proceeded to the general subject of the removal of uterine fibroids by abdominal section, which he said was a very important one He pointed out that operators were to be divided into two schools, the one preferring to treat the pedicle by the intra peritoneal method, the other preferring the extra peritoneal The advocates of the former based their arguments on the success which has resulted in the operation of ovariotomy, from the introduction of the intra peritoneal ligature of the pedicle But it was scarcely necessary for him to show how fallacious such reasoning was, for the conditions were so dissimilar It was true that there were many different forms of ovarian pedicle it might be large or small, long or short, broad or narrow, thick or thin, but they were all essentially of the same character, and capable of being more or less easily secured by ligature, which might be confidently relied on if properly applied On the other hand, the uterine stump is very different It is composed of muscular fibre, white and yellow elastic tissue, forming a structure so peculiar that, under the pressure of a ligature tied with as great a strain as it will bear, it yields before the compressing force to such an extent that in a few hours the ligature may be quite loose This occurs even when the pressure is exerted with the aid of a screw, and he pointed out to those who were present at the operation that at the first tightening of the screw there was complete arrest of the bleeding for the time, but that at intervals of ten or fifteen minutes the screw would take a turn or more with facility In this way an amount of constriction was attainable which, if attempted at once, would probably lead to the breaking of the wire or the cutting of the tissues He had just come from the meeting of the American Gynecological Society, where he had read a paper on the subject of the treatment of the pedicle, and where the opposite school was so well represented in the person of Dr Martin, of Berlin, and he had the satisfaction of feeling that, for the time at least, he had established his position

Now the pedicle in this operation varies very much, not in the nature of the tissues forming it, but in the extent and manner in which the parts are involved Thus the tumor may spring by a distinct pedicle from the fundus, or some part of the free surface of the uterus In such a case the application of the extra peritoneal method is very simple, and his results have been uniformly good, for in thirteen of these cases, all the patients recovered On the other hand, of all the cases of this kind treated by the ligature and intra peritoneal method, five in number, only one was successful Moreover, he had attempted the method in several cases and had been obliged to resort to the extra peritoneal method after failure of the ligature, though preceded by compression with very powerful forceps When the body of the uterus is extensively involved in the growth, then matters may be very much complicated The broad and ovarian ligaments may be so lax that it is a simple matter to include ovaries and uterus in one encircling loop Such a case is little more difficult than an ovariotomy done with the clamp But the ovarian ligament may be so short on one side that it has to be ligatured separately That had to be done in the case that furnished the occasion for these remarks As a rule it is advisable, in such a case, to secure the uterus and other ovary first, to transfix the stump with the supporting pins placed across the ab-

dominal wound, to cut away the tumor, trim the stump, and then remove the ovary, lest in tightening the instrument any part of the ovarian pedicle should be pulled through the loop of the ligature In the case under consideration it was not necessary to observe this order, as the broad ligament on the left side was very lax, while the ovarian ligament was very short On the right side the ovary could be raised quite out of the pelvis Sometimes both ovaries are thus tied down and have to be secured separately The same precautions must be observed

But the disease may involve the whole body of the uterus properly so called Then we must make a pedicle, and this is the most difficult state of things to overcome It was for such a state of things he had devised his method of partially enucleating the body of the uterus and the lower portion of the tumor The large vessels of the ovarian plexus are secured on each side by two pairs of forceps or stout ligatures, the lower of each pair being placed an inch higher than the level of the proposed constriction Then the peritoneal investment is divided all round on a level between the upper and lower forceps, and reflected downward toward the cervix and nearly to the level at which the loop of the serre-nœud is to be applied In doing this it is necessary to seize the peritoneal edges with forceps placed at intervals of about an inch When the reflection is completed these instruments are collected and raised up and the wire loop is applied outside of the peritoneum Sometimes, and especially when it is desirable that the patient should not lose much blood, it is well to throw an elastic ligature around the uterus and broad ligament as soon as the division of the peritoneum is effected Applied in this way, it serves to draw in the broad ligaments toward the uterus and to enucleate the tumor It is to be removed as soon as the serre-nœud is applied—above or outside it, of course In this way an inch or more in the length of the pedicle may be gained Remember, that in this method it is necessary to have the stump so long that the whole of the constricted portion must be outside the peritoneal cavity, in which position it is to be retained by the transfixing pins which pass through the stump just outside the wire loop and rest on the parieties on each side of the wound While the peritoneum is being reflected, the tumor should be held up by the assistant, and thus it rises gradually out of the pelvis with the pelvis with the uterus One precaution to be observed very carefully in these cases, is to transfix with the pins *before* cutting away the tumors He once lost a patient through the non-observance of this precaution The last steps are to cut away the uterine tissue to within a quarter of an inch of the pins, and to trim the loose peritoneum by cutting it away to within half an inch of the loop and then stitching it from opposite sides across the surface of the stump to hold it well together Before closing the wound give the screw a final turn if it will allow of it Remember that the distal portion of the stump must slough off, that it is desirable that the amount of this tissue should be as small as possible, and that it is necessary to keep it out of the peritoneal cavity You may have heard great stress being laid upon the character of the mucus in the uterus and cervical canal, and you may have observed great care used in wiping it away and setting aside the sponge employed for the purpose One operator has gone so far as to pass an iodoform pessary down the canal for the purpose of disinfecting This is a practice with which he has no sympathy, nor is it rational or founded on any sound reasoning He looked on it as a bugbear and regarded it as a means of withdrawing attention from other and more important matters of detail As to comparative results, Martin had just reported 84 cases with a mortality of 25, while Dr Bantock was able to point to 72 cases with only 12 deaths

Listerism—There is some misapprehension of the value of terms Some operations are termed *aseptic*, but the result only can prove any operation to have been aseptic All operations are or are not performed upon an antiseptic method Dr Bantock has now discarded all antiseptic agents When Listerism was first introduced, he used it in all its details, and continued to do so until he lost a patient, and had others affected by, what he felt sure was carbolic poisoning An easy and sure test for this is the absence of sulphates from the urine In one case of carbolic poisoning the temperature rose to 107° and the patient was almost moribund, by means of wet sheets and ice packing the temperature was brought down to normal in eight hours and she recovered In one fatal case the kidneys were found congested, there had been acute suppression of urine After this experience he gradually reduced the strength of the carbolic washing fluid to 1 per cent Coincidently the proportion of sulphates in the urine increased and there was an absence of high temperature and other symptoms of hitherto unknown origin Now, as 1 to 40 is the weakest solution that can be useful as a germicide, a 1 per cent solution could serve no good purpose, and the carbolic acid was omitted altogether Afterward he tried doing without the spray and results steadily improved Of his last 100 ovariotomies only three had been lost, and of the last 78 only one But ovarian statistics do not apply to uterine operations

DR W H PARISH was present at the operation the day before, and it was a complete illustration of what is necessary in all operations *First*, in saving blood, Dr Bantock was very careful to use hæmostatic forceps to secure every bleeding point in the abdominal wound before opening the peritoneum The same economy of blood was observable in every step of the operation Great care was also taken to avoid shock from cooling the intestines by the contact of air and consequent evaporation Large flat sponges were pressed in to cover the intestines and prevent their escape or the entrance of blood or discharges into the peritoneal cavity He is extremely careful about the cleansing of his sponges before re introducing them into the wound *In* placing sutures, he first passed several silkworm gut stitches close to one another near the stump After the wound was entirely closed it was covered with clean absorbent gauze, a pile of this was placed over the stump The whole was secured with a cotton binder,

using no adhesive plaster So while using no germicide at any time, every care was taken to make the operation an aseptic one Would Dr Bantock consider it safe to transfix, ligate and drop the pedicle in case of a uterine fibroid having a thin pedicle as long as a finger? Dr Parish had done so on one occasion and the patient died

Dr Bantock replied that a uterine fibroid with a finger like pedicle he had never seen He has observed none smaller than half his wrist He thinks the extra peritoneal method safer in every case

Dr. Longaker made some remarks on securing the peritoneum over the base of the stump, and asked what kind of suture Dr Bantock preferred for that purpose?

Dr Bantock said that any kind of suture would do, it was merely to secure a neat stump that would not spread out over the wound He prefers fine silkworm gut for sutures He introduces his needle from within, close to the edge of the peritoneum, and makes sure of a hold in muscle or aponeurosis and then through the subcutaneous fat and skin, to secure a firm hold and prevent future hernia.

(To be concluded)

CHICAGO MEDICAL SOCIETY

Stated Meeting, October 3, 1887

The President, Wm T Belfield, M D, in the Chair

Dr F Henrotin, read a paper on

Resection of the Intestine for Fæcal Fistula

(See page 713,)

Dr D W Graham The method of treating the mesentery and of stitching the ends of the bowel together raises legitimate questions for discussion, but if this case proves anything it proves that the doctor was correct, although he deviated from what is generally considered the best method I have never been able to see why a V-shaped piece of mesentery should always, and necessarily in exsection of intestine, be taken out Certainly it is safer not to do so, safer in regard to the establishment of the circulation in the bowel, and therefore ought to give better results The apparently superfluous fold of mesentery can be taken care of in some such way, as was done in this case, and rendered harmless In regard to the stitches, it is impossible to say whether the patient's chance of recovery would have been better with the Czerney Lambert stitch than the one which was used, the patient having got well, the inference is that this method is safe

I had an experience in opening the abdomen in strangulated hernia It was a case that had been strangulated for nearly a week The attending physician had etherized the patient on Saturday and reduced the hernia, apparently When I saw the patient on Thursday following, there was stercoraceous vomiting, very marked, great tympanitis and all the signs of obstruction and strangulation, yet there was no external appearance of hernia On consultation it was decided that the abdomen should be opened in the central line This was done at once, and on introducing my hand I found a knuckle of intestine in the internal ring On attempting to reduce it from within some force was cautiously used, more than I now think ought to be used when strangulation has existed any length of time This failing, it was decided to cut down upon the inguinal canal and approach the hernia from that direction The knuckle was found and released by the proper incision, was carefully examined and judged in a condition to be returned I am satisfied that in that case the bowel could not have been freed by traction from within without rupture The question raised, of attempting to reduce hernia by laparotomy and traction from within, was discussed not long ago by a London surgeon in one of the medical journals. I have no doubt that certain complications of strangulation can be better managed by laparotomy, but I am sure that if we attempt to reduce many ordinary hernia in this way we will get into trouble

Dr A B Strong I only wish to say one word in regard to the manner of suturing the intestine. It simply shows that the manner of suturing makes no difference so that you manage to bring the serous surfaces together The sewing together of all the coats of the intestine was something new, but the operator fortified that with a row of sutures bringing together simply the peritoneal coat, which I think was the essential thing Sutures through the entire bowel of course added strength to the gut. I must say in reference to the mesentery that I never could see any special reason for taking out a V shaped portion of it, it seems to me that the manner in which it was treated was preferable, as it would increase the strength of the bowel

Dr Henrotin, in closing the discussion said When I came to the mesentery it folded up so naturally that I had no hesitancy in putting in my stitches very carefully on one side only so as not to interfere with the circulation I allowed no stitches to go through and strangulate the mesentery I knew that if the mesentery was moved it would stretch the bowel and strain the stitches In regard to the stitches, Gregg Smith (who has just published a work on abdominal surgery) is the man who told me how to put them in It seems to me if you take a continued stitch and bring the serous surfaces together only, that it tears easily And when it is necessary to return the bowel at once, and the patient tosses about much in bed immediately afterwards, unless you take considerable of the muscular coat and make a firm union the stitches are liable to tear through. I had two or three of my serous stitches that were about a sixth of an inch in length tear through and I had to commence over again I would like to know one thing would the turning in of the bowel and the consequent lessening of the caliber have a tendency to produce stricture of the bowel afterwards? If not, I feel certain that this is the best method, and do not think there is much danger of stricture high up in the small intestine from such operations

DR ELBERT WING exhibited a specimen of

TUBERCULAR ULCERATION OF THE LARYNX

This specimen comes from a case that was posted at the County Hospital this afternoon, a man 35 years old, with chronic tuberculosis of the lungs For a long time he had had symptoms of tuberculosis of the larynx and the diagnosis was made by means of the mirror The only spot of special interest about the post was this larynx and the œsophagus Both lungs were considerably involved in tubercular infiltration and ulceration, with large cavities There was also tuberculosis with ulceration, of the intestines limited to the colon, and the hypertrophy of the glands of the mesentery There is one ulcer of considerable size at the base of the epiglottis on the left side between the epiglottis and the tongue The anterior surface of the larynx below the epiglottis clear down to the edge of the arytenoid cartilage is one immense ulcer, the floor is irregular, the vocal cords, both true and false, are almost entirely lost through ulceration and erosion There is also evidence of rather marked trachitis, which would be associated with such a case The mesenteric glands were uniformly enlarged, most of them the size of a small bean, and a point of interest in their location was that those that lay immediately along the bowel were the largest In looking up the subject I find no reference of any consequence to tuberculosis of the larynx, except in Eichhorst and Strumpell The latter says that in 25 per cent of the cases of tubercu losis of the lungs there is also tuberculosis of the larynx He says these statistics are vitiated because careful observations are not uniformly made and a great many cases do not come to the post mortem table Eichhorst quotes a writer, Williglk, who reports 1317 cases of tuberculosis examined in which 13 8 per cent had involvement of the larynx This man claims that 49 6 per cent of all cases of tuberculosis of the lungs have also tuberculosis of the intestines This specimen is of special interest because so large a surface is involved Theoretically, it is of some interest to remember that there may be ulceration of the larynx associated with tuberculosis of the lungs in which the ulcers are not tubercular

SUDDEN GLYCOSURIA UNDER GASEOUS ENEMATA

DR FRANK BILLINGS called attention to something that happened in a case in which he had been giving gaseous enemata for pulmonary tuberculosis The patient had been treated for about two months and has taken about fifty enemata Two weeks ago he suddenly complained of great thirst, and at the same time said he had to rise several times at night to urinate An examination of his urine showed a specific gravity of 1 040 Dr Billings did not know just how much he passed in 24 hours, but it was a great deal This glycosuria certainly occurred suddenly, and he thought that perhaps it might have some connection with the enemata In medical books we find it stated that diabetes has a certain relation to tuberculosis It may be the predisposing cause, or, conversely tuberculosis may excite diabetes He immediately stopped the enemata and placed the patient upon arsenite of bromine, and small doses of codeia Two days before the meeting the specific gravity was 1 025, and the patient does not rise at night to urinate

SUDDEN DEATH AFTER URETHRAL INJECTION

DR W T BELFIELD related an accident that happened to a member of the Society, and which is likely to happen to any one at any time A physician cut a slight stricture of the urethra about ¾ of an inch behind the meatus It was done under cocaine without trouble or pain The doctor had the patient come to his office every second day to pass a sound, and each time gave him an injection of a 4 per cent cocaine solution, about 2 drachms, before introducing the sound On the seventh day after the cutting the patient complained of being very nervous, had been nervous for several days and had not slept at night The sound was introduced that day under cocaine as before On the ninth day he returned, and an injection of cocaine was given The patient reclined on an ordinary office chair and the doctor turned away to procure his sound and warm it while the cocaine should exercise its influence on the urethra, in less than a minute after the cocaine was given the patient complained of dizziness and fell back on the chair Another physician in the outer office was called and together they did what they thought necessary, administering stimulants, and using a galvanic current, but in three or four minutes after the injection was given the young man was dead He was about 28 years of age, and had been in good health so far as is known At the post-mortem examination the body was thoroughly examined, the brain included, there was absolutely nothing abnormal found except that the kidneys were enormously congested, they were so blue that they looked like an ordinary spleen The cause of death is open to conjecture, probably the patient was suffering from uræmia, and any irritation of the urethra would have provoked the result, certainly death could not have resulted from cocaine poisoning, since sufficient time for its absorption and circulation had not elapsed, nor is it plausible to assume that there had been an accumulation of the drug from the previous urethral injections Doubtless an injection of distilled water would have provoked the same result Whether the urine had been scanty or albuminous the attending physician could not say

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

DR F I KNIGHT, CHAIRMAN

ALBERT N BLODGETT, M D, SECRETARY

Regular Meeting, Wednesday, October 12, 1887

(*Concluded from page 702*)

DR F W STUART read a paper on

A CASE OF SO CALLED VICARIOUS MENSTRUATION

The case which I am to report to night I saw at the Carney Hospital, from October, 1885, to March

1, 1886, during the terms of service of Drs J O Otis and J J Minot, and afterwards at the patient's home, until a few weeks before her death It was suggested to me that the case was very interesting, and that it might be well for me to report it, since I had followed it longer than any other physician I am indebted to Dr Minot for the use of the careful notes he made during the time the patient was under his care

I first saw the patient in October, 1885 She was then fifteen years old, and the following history was obtained Her grandfather, father, four paternal uncles and aunts, and two paternal cousins, had died of phthisis, and two more cousins were then "in consumption" The patient had never been strong since 3 years old, had vomited often, and had frequent "sick headaches" She was always feverish, vomited every night if she ate a hearty supper, and so had been accustomed to limit that meal to a glass of milk The bowels were always constipated, and she took pulv glycyrrhiz co continuously She frequently had sore eyes In 1882, she had typhoid fever

November 24, 1884, the catamenia appeared for the first time, lasted two days, were unattended by pain, but since that time the patient had never menstruated At the next catamenial period, she vomited everything she ate for two or three days, and the vomiting was repeated at each period, when she also had a feeling of weight and soreness in the lower abdomen At times, she had a pain in the right ovarian region, when a "bunch" could be felt there, though both pains and "bunch" occurred at non-menstrual periods She had no trouble with micturition In May, 1885, she had an epileptic fit According to the hospital records, she was treated, in April, for a naso pharyngeal catarrh, where a note is made, stating that a few days previously she had had an hæmoptysis, though in October she did not refer to it From December, 1884, to June, 1885, she vomited only at catamenial periods, never between In June, the vomiting began to be much more frequent and severe, anything but milk being vomited In September, after long vomiting, she raised a little blood, and this was repeated several times She complained of great pain immediately after eating, and vomited without any signs of nausea appearing

Such was the history of the case up to October, 1885, though there seemed to be a large element of hysteria in the case, and her truthfulness as regards symptoms appeared rather doubtful The patient was pale, anæmic, and poorly nourished, but physical examination was absolutely negative, with the exception of localized tenderness in the epigastrium The diagnosis, it was thought, rested between gastric ulcer and vicarious menstruation She was put on pancreatinized milk, and all went well until the end of the month, when the usual symptoms appeared, and even this milk was not retained She now visited a "clairvoyant doctor," and afterwards a quack in New York City, who told her she had an imperforate hymen, which must be cut She wished advice as to the cutting, but examination showed a normal hymen, as was to be expected from the history of a previous menstruation On December 24, she visited the hospital after one of her attacks, and from that time up to March 1 careful notes of her condition were kept On that date, December 24, she stated that, during the attacks, she had pain in her stomach as soon as food was swallowed, and this pain increased, and was accompanied by a loud, rumbling noise She never belched wind, or passed any per rectum After two or three hours of this pain she vomited, but evidently not undigested food She never vomited directly after taking food, nor in less than two hours after its ingestion After vomiting, the pain gradually passed away in about one hour

December 22 She was sitting quietly, began to choke and then raised some blood, less than a teacupful she said She did not vomit at all, but coughed

On the night of December 23, and the morning of December 24, while fasting, she raised dark, thick blood She had no cough, usually ate no breakfast, has had night sweats She sat up late nights, ate very little, danced a good deal, and slept poorly Examination, superficial, owing to the recent hemoptysis, showed the patient to be small, poorly developed, pale and anæmic No enlarged glands were to be seen or felt Auscultation gave an almost puerile breathing, and expiration slightly prolonged There was localized tenderness, limited to a small area over the epigastrium She was told to take peptonized milk every two hours

December 25 She raised blood four times Each time she first began to choke, and then raised the blood, which was greater in amount than at any time before She had considerable cough, complained of pain in the lower abdomen The peptonized milk was retained She was given ext ergotæ fl Her mother stated that the vomiting occurred at about the 25th of each month, and lasted one week She did not think the patient vomited in the intervals The blood seen before the last attack was mostly streaked through the vomitus, but, at the last attack, was as stated by the patient

December 31 The patient said she felt better There had been no vomiting, and no raising of blood since the 25th Her weight, which had been ninety-two pounds, was now reduced to eighty seven pounds Examination gave a percussion note a little higher in the second interspace on the right than on the left side There was also a slight difference in the back, between the scapula and the spine, the left being the higher Auscultation gave nothing abnormal Heart normal The lower thorax was long and pointed There was marked tympanitic resonance on the left side of the upper abdomen There was nothing to be seen or felt There was tenderness in various spots, in the epigastrium, about the umbilicus, and about the edge of the ribs on the left side She was given malt and the syrup of the hypophosphites

January 12 She stated she had been thirsty of late, and had vomited after drinking much water

January 15 She had severe pain for two hours

after eating some turkey, and then vomited, but the pain lasted about three hours longer

January 19 Seemed better, had not vomited or raised blood in the few days past She had, from the vagina, a discharge of a yellowish matter, streaked with blood She complained of pain in both iliac regions

January 20 Was unable to urinate, and a sitz bath and spts ætheris nitrosi were given

January 22 Vomited a little after a breakfast of beefsteak, but the vomitus consisted only of bile Urination was all right

February 3 She stated that she had been away on a visit, and, at night, was laughing, when she began to cough, and raised a tablespoonful of dark, clotted blood She did not vomit During the night she awoke with a "pain in her belly," and the next morning, after taking some milk, she vomited The vomiting continued all day, but the next day the patient was better, complaining only of a sharp pain in the lower abdomen She had more discharge from the vagina than formerly An examination of the chest showed nothing abnormal The patient was referred to the gynæcologist, who reported everything normal about the external genitals, and would examine further only under ether From the history he obtained he was inclined to think the case one of vicarious menstruation

February 19 The patient returned, and stated she had been quite well up to the 11th, when, after going to the city, she vomited sour food, but no blood On the 12th she was better, but vomited again on the 13th, up to which date she felt well, but then she had pain in both groins, so severe that she was doubled up Before and during the pain, she had passed bloody urine during several hours, and at frequent intervals afterwards, she passed a urine which was pale, clear and not bloody, but in small quantities For a few days, the pain returned in the afternoon, though she passed no blood

On this date, the 19th, the patient said she felt well, though she was weak, and had no appetite She said she always had diarrhœa during the attacks of vomiting, but at other times, she had marked constipation Walking and riding in the horse cars, she said, always brought on the pain, though she could ride in a carriage without experiencing any trouble She was very nervous, easily startled, and said she had "nightmare"

On Feb 23 she presented no definite symptoms

I have alluded to treatment a few times, but have not intended even to outline it Symptoms were met as they arose, but the main object kept in view was to give a thorough course of tonics, which was done by the exhibition of iron, arsenic, extract of malt, and syrup of the hypophosphites almost constantly.

After March 1st the patient did not return to the hospital, and, indeed, discontinued treatment I was, however, interested in the case, and made weekly calls to keep myself informed as to her condition This did not seem to change much, though she grew weaker constantly, and coughs, night sweats, and loss of strength became the predominant symptoms Towards the end of April I again examined the chest, and found evidences of consolidation at both apices The patient now developed a fever, which remained for weeks at about 102 5°, diarrhœa of a very severe character set in, and the patient rapidly sank, and died in about two months

Unfortunately, no autopsy could be obtained

I feel some diffidence in giving my opinions regarding a case so difficult of diagnosis as this Still, I will venture to offer a few remarks concerning the diagnosis

In the first place, it is certain that the patient died of a florid form of phthisis I do not think that she had a gastric ulcer To be sure, there was vomiting, sometimes hæmatemesis, and localized tenderness, but, opposed to this, the patient never vomited until two or three hours after the ingestion of food, and the blood vomited only streaked the vomitus Beyond this, there were days when she retained hearty food, and the gastric symptoms were limited to certain periods

I believe, then, we are to consider three affections as possible during the earlier part of the trouble, namely, vicarious menstruation, the hysteric gastrique of the French writers, and phthisis

No one of these meets the case satisfactorily The manner of vomiting, and the character of the vomitus—partially digested food, streaked with blood—suggest the hysteric gastrique But later, there was hæmoptysis, that is, the blood was coughed up, not vomited, came probably from the respiratory, not the digestive tract

Vicarious menstruation may occur from both tracts, but there had been normal menstruation, and the absence of the menses was only to be expected in one so poorly developed and anæmic Again, the vomiting of blood was only a comparatively late symptom, and, notwithstanding the patient's assertions, no direct connection with menstrual trouble could be definitely established In December she coughed up blood, but did not vomit, in January she vomited, but raised no blood in any way, and there was an apparent attempt at menstruation, and in February there were no definite symptoms Both of these affections are extremely rare, and both offer such difficulties in the way of diagnosis, that it is only after a very careful study of the case that one is warranted in making such a diagnosis Either may have obtained and been followed by phthisis

It is a question with me whether there was ever any disease beyond phthisis To be sure, it is hard to reconcile all the symptoms of this patient with this view, especially when such careful observers as the gentlemen mentioned failed to find signs, but it is the one disease which every one connected with the case constantly looked for, and it is the one which caused the patient's death The uncertainties of the case prevent an absolute diagnosis, and were a constant source of annoyance in treating the case

DR BLODGETT said I would like to ask if any medical person witnessed the expectoration of blood at any time?

DR STUART. No, it was something that we at-

tempted to do, I gave notice to the mother to call me at any time that the patient raised blood My office was only a block from where she lived, but they never sent for me The mother was hysterical, as well as the girl, and we thought she had a little more than her daughter did That was one of the elements that was pretty hard to determine It was hard to say whether she vomited the blood or raised it by coughing She insisted that the vomitus was streaked with blood after severe vomiting That we could see ourselves She afterward said she coughed up thick blood, that we never saw

DR. J L FOLEY asked whether the blood were dark or scarlet?

DR STUART replied that the patient said it was dark If it were from the air passages of course we would expect it to be bright

DR BLODGETT said I have had the opportunity of examining three cases where the presence of blood was important One of these was a case where the blood was expectorated by the patient, to the great alarm of the family and the consternation of the physician, who could find no legitimate cause for it It was finally made evident that the patient wilfully and voluntarily produced the blood from somewhere within the oral cavity It was satisfactorily determined that the blood did not come from the stomach or lungs, but from some mucous tract above the œsophagus or trachea A second case which came under my observation was one in which it was believed by the medical man and by the patient that an actual hæmoptysis had occurred, in which the blood followed coughing and was produced in a fresh or comparatively fresh condition, although never frothy That was finally, by close study, found to be due to an oozing from the nasal or pharyngeal mucous membrane, which trickled down into the larynx, and then was coughed from the upper portion of the respiratory tract No symptoms have followed the accident, and they have for many months been carefully watched for Once or twice it has been noticed in other members of the same family, but it seems to be due to a peculiarity of the patient, and not to organic disease

The third case was one in which, absolutely, blood was lost in large quantities, sometimes in quantities estimated at from a teacupful to half a pint I have never seen the hæmoptysis going on, but I have seen the blood which was produced after the expectoration had ceased This blood was supposed to come from the lungs In consultation, a physician of great experience and eminence pronounced it blood of pulmonary origin On one occasion I was fortunate enough to see the blood which was formed in distinct coagulæ The nurse, who was competent, said that it was found in the mouth in that form, so that the finger had to be used to break up the clumps This showed that it did not come from the lungs, but from some other part of the body, and I came to the conclusion that it all came from the stomach The autopsy showed that it came from the exudation of blood through the wall of the stomach without ulceration There was no other source from which it could have been derived The lungs were diseased but there were no cavities, and no signs of a pulmonary origin of the hæmorrhages There was no crackle, which usually follows the effusion of blood into the pulmonary tract These three cases have been of interest as presenting three conditions, in each of which the expectoration of the blood was the principal symptom, each of which seemed to analyze itself into a different form from the others, and that is the reason why I asked the question whether any medical person had seen the expectoration going on in this particular patient

DR VICKERY I would like to ask Dr Stuart how regularly, according to her own statement, the loss of blood was Was it at just the right time?

DR STUART Everything depends on how a man reckons the right time She said that she began about the 18th to feel bad, on the 23d she began to vomit, the vomiting lasted just one week, and then it all let up until the next 18th This was the same whether the month had twenty eight or thirty one days

DR VICKERY How many months were there?

DR STUART From October to January At each period the symptoms differed She came to the hospital in October, and said that she had had the vomiting in September We took her word for that, and then the question was whether she had gastric ulcer She was told to go home and eat a good hearty meal She came back and said "Doctor, the moment I took it I vomited" We put her upon pancreatized milk Her vomiting began in June, but she raised no blood then In December she "coughed" up the blood, but did not vomit any In June she had made an apparent attempt at menstruation At one time previously she had had a discharge of blood from the anus

DR VICKERY The hæmorrhage was seen?

DR STUART Yes, she did have hæmorrhages Each time there was blood somewhere

DR BUCK Did she have a small thorax from tight lacing?

DR STUART No, she never wore corsets

DR VICKERY I don't think the slightest belief should be given to hysterical patients One once brought me some live earth-worms which she declared she had vomited That well illustrates the unreliability of this class of patients

DR STUART The chief interest seems to centre upon this, the girl was an only daughter The mother was a widow and thought everything of the girl The father died of phthisis There was phthisis everywhere in the family We asked the question, Is this phthisis? We found no signs in the lungs The question of vicarious menstruation was raised It seems to me that the whole thing from beginning to end may be phthisis A physician in Boston told me he was called to see such a case out of town He found the patient with marked signs of phthisis, cavities in both lungs The attending physician, who was a man with a large practice, said that it was vicarious menstruation, and that when puberty was established the child would get well In this case I can only suppose that she had phthisis, and we did not get the signs Dr Bowditch exam-

ined her once She was examined by several other gentlemen, all of whom pronounced her entirely free from signs Still, I believe that phthisis was there I think the whole thing was phthisis

DR FOLEY Did she have any of the symptoms of phthisis, as distinct from the physical signs?

DR STUART She was feverish all the time, she said She also had night sweats She said she did not have much cough but I do not think any reliance was to be placed on that

DR KNIGHT How long from the first blood to the appearance of physical signs?

DR STUART Seven months, from October to April

DR KNIGHT It seems to me it must have been the experience of all physicians who have seen such cases, that patients not infrequently have hæmoptysis come on sometimes for months or years before the appearance of physical signs I have frequently met such cases It is quite the rule, I should say, for patients to have hæmoptysis, and then phthisis after six months It seems to me that it is not inconsistent with the development of tuberculosis Supposing when you first examined the case you had found physical signs in the lungs The question of menstruation would not have entered your head

DR STUART Certainly not

DR KNIGHT Why the difference?

DR STUART She was so positive that it occurred so regularly They questioned her vomiting blood as she said, but certainly I saw vomitus that was streaked with blood

DR KNIGHT Do you think that gynecologists would accept the fixed date?

DR STUART No, I do not think so My view of the case was that it was phthisis That the vomiting that we had here was hysterical That the periods came so was due to the hysterical condition of the patient I don't see why a phthisical patient might not vomit every three or four weeks It is very easy for a man to be misled, I think In this case vomiting occurred every three or four weeks in the course of the phthisis In regard to the question of hysteria, it was admitted by the other physicians who saw her, that her statements were all open to doubt It does not stand on my own authority

DR BLODGETT then exhibited the following *new instruments*

A STETHOSCOPE, WITH A MEMBRANE ARRANGED IN THE BELL EXTREMITY

in such a manner as to intensify the sounds Of its efficacy he could not speak, as he had not tried it It also had the merit, the advantage of which was first pointed out by Dr Haven, of having the flexible tubes so long that the examiner may keep at a greater distance from the patient The value of this is seen especially in the case of children, and patients infested with vermin, or in persons in whom the breath is unusually offensive

THE AVITREOUS THERMOMETER

Its chief advantage is in the fact that it will not be readily broken Some of the members would criticise it on the ground of cleanliness, since it has lines of union which would be difficult to keep free from impurity

A NEW DOUBLE CATHETER

The return current is by a series of channels formed by the urethral wall on the outside, and grooves in the metal on the inside It may answer a useful purpose when it is desired to wash the surface of the urethral membrane

A SERIES OF ANTISEPTIC INSTRUMENTS WITH AN ADJUSTABLE HANDLE,

which allows the metal portions to be readily removed, and thus be subjected to cleansing processes that the ordinary handles would not permit The instruments were kindly loaned by Messrs Leach & Greene

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Effects of the Subcutaneous Injection of the Septic Vibrion—Toxicity of non febrile Pathological Urine—Treatment of Ingrowing Nails—Nature and Origin of Leprosy—Dupuytren's Contraction and Progressive General Paralysis

At a recent meeting of the Société de Biologie Drs Charrin and Roger read a paper giving the results of their combined researches on the effects determined on dogs by the subcutaneous injection of septic vibrion This microbe, according to these authors, does not cause the dog's death, as it does on the rabbit and the guinea pig, but only a local lesion They further stated that the first inoculation generally confers immunity on the animal, and with one exception, the dogs operated on became refractory to a second inoculation M Chauveau, Professor of Experimental and Comparative Medicine at the Faculty of Lyons, asserted that these results are quite similar to those he has obtained with the microbe of gangrenous septicæmia, which is analogous to the septic microbe

In a very interesting paper by Dr V Feltz on the toxic power of non-febrile pathological urine, the author, in referring to a previous note in which he demonstrated that the toxic properties of febrile urine are far greater than those of non febrile urine, explained that this fact does not result from the density of the former He has made a series of experiments upon the noxious action of febrile urine, taken from glycosuric, albuminuric and icterous patients, and from patients who were cachectic through cancer or anæmia The urine employed was quite fresh, filtered, and analyzed He then heated it to the temperature of a dog's body and injected it into its vein The result showed that glycosuric urine of non-cachectic patients is not more toxic than normal urine Icterous urine resulting from serious renal lesion, and urine of patient's affected with cancerous cachexia or serious anæmia, are considerably more toxic than normal urine The symptoms observed during the

experiments, the kind of death which follows, the disturbances revealed at necropsy are similar to those observed when normal urine is injected in sufficient quantities to cause death From this the author concludes that it is the augmentation of the noxious principles that determines the degree of toxic action of pathological urine, and that the salts of potassium contained in urine are the principal agents in uræmic poisoning

Dr Patin, of Boulogne, has published in the *Gazette des Hôpitaux* a note on the treatment of ingrowing of the nail, and as it is a most painful affection, any remedy for its cure or relief without operation will always be welcomed by sufferers The treatment consists in first giving the patient a hot foot bath, rather prolonged, and after having thoroughly wiped and dried the part, Dr Patin introduces into the interstices of the nail, a solution of gutta percha in chloroform (10 parts of the former to 80 of the latter) which is known at the Hôpital Saint Louis under the name of "traumaticine," and employed there with success by Dr Besnier in the treatment of psoriasis These applications are made frequently for the first few days, and then at longer intervals Great relief is obtained by the anæsthetic action of the chloroform If the patient would restrict the treatment to these applications avoiding at the same time to excoriate the flesh or to injure the nail by frequent cleaning and scraping, if he has the patience to wait until the nail had sufficiently grown to enable the surgeon to cut it transversely in, taking care to blunt the angles slightly, finally, if during some time he will avoid, as much as possible, walking, and would use shoes or boots sufficiently large, complete and durable cure It is easy to comprehend the rationale of this treatment, but it is sometimes necessary in order to complete this protective dressing, to cover the diseased toe with sticking plaster, which should be renewed after each application Dr Patin asserts that he has treated several cases by this method and with perfect success

Dr E Besnier, whose name has been referred to in the preceding paragraph, is a dermatologist of some repute At a recent meeting of the Academy of Medicine, this learned physician read a note on the nature, origin and transmissibility of leprosy which he concluded by the following propositions Far from being a malady extinct, leprosy holds, on the contrary, a large place in general and international epidemiology, and it presents for this country a direct interest It is neither a spontaneous malady, nor an accidental or toxic affection, it is a malady exclusively human, specific, with a bacterian element determined It is transmissible in conditions partly unveiled, partly still obscure, man seems to be the only agent of this transmission, it is nearly certain that it can be inoculated, during vaccination for example, it is certain that man transports it from one place to another and that it remains attached to him, not to the soil, it is certain that it may be contracted by heredity, but the heredity peril is infinitely less than is still believed Extrinsic conditions, such as social misery, and sordid promiscuity, favor the propagation of the malady, the inverse conditions almost annihilate its contagious faculty In these conditions medicine can oppose to leprosy a prophylaxy which would be efficacious, based as it would be on the progress of hygiene and general sociology, without having recourse to the cruel procedures of a past age, and in remaining faithful to the principles of liberty and humanity which are the greatest glory of our epoch "

Dr Régis, of Bordeaux, read a note at the last meeting of the Association Française pour l'Avancement de Science, on the case of a patient suffering from Dupuytren's malady coexisting in progressive general paralysis, which the author summarizes as follows 1 Dupuytren's malady (retraction of the palmar aponeurosis) is really, as there is a tendency to believe, the manifestation of a general state which is nearly always that of arthritism and not a local affection of traumatic origin 2 The manifestations of gout and those of general paralysis may coexist and be confounded in the same subject, so that one is forced to conclude as to the reality of a morbid relationship already admitted to a certain extent, and which new facts will certainly confirm and more and more elucidate Another member observed that diabetes frequently accompanies the retraction of the palmar aponeurosis A B

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

An Acid that Destroys Sweet Taste—Vomiting of Gall Stones—New Method of Ventilating—Hæmatometra with Degenerating Fibro Myoma—Diseases of the Bible—Indian Hemp in Persistent Headache

A new acid has been extracted, from the leaves of the plant known to botanists as gymnema sylvestra, by Dr D Hooper It is a plant of the family of asclepiadiæ, which grows in India A few drops of the acid well diluted are found to cause all sense of the sweet taste of sugar to disappear as if by magic For instance, if gingerbread were eaten, only the taste of the ginger was perceived, if a sweet orange, only the acid flavor of the citric acid But what is still more curious, not only the sweet taste of substances containing sugar is effaced, but bitterness is also destroyed at the same time Hence, if a person takes sulphate of quinine after a few drops of the acid, it merely tastes like so much chalk or plaster of Paris The effect in question lasts, as a rule, for one or two hours, and then the sense of taste returns to its normal condition The active principle of the leaves of this plant appears to be soluble in water, alcohol, ether and benzol The aqueous solution of the substances soluble in alcohol has a decided acid reaction, and the author extracted an acid from it not unlike chrysophanic acid in some respects To this new product has been given the name of gymnemic acid, and its anti sweet and anti bitter properties are considered by Dr Hooper to point to its becoming a valuable addition in prescribing, and in a short time he intends to publish a paper upon its various actions and uses

An interesting case of vomiting of gall stones has just occurred under the care of Dr F M Pope.

When first seen the patient, a stout woman with fresh complexion, had marked tenderness and a sense of resistance in the right hypochondrium, hepatic dulness was not increased, and there was no humor The urine contained no sugar or albumen, she had had vomiting at frequent intervals for about five weeks Two days later she had a considerable increase of pain, accompanied with internal strabismus and slight convulsions, however, she was not unconscious During the day she vomited two gall stones of about five eighths of an inch in diameter, with six or eight facets on each, and several smaller ones For the next two days she both vomited and passed several gall stones, but eventually died, collapsed through combined vomiting and diarrhœa, twenty four days after Dr Pope first seeing her At the post-mortem examination nothing abnormal was seen in the abdomen, no general peritonitis, no excess of peritoneal fluid, but on raising the liver the gall bladder was found to be situated in a circumscribed abscess cavity, formed by the adhesion of the neighboring organs The gall bladder itself was in a sloughy condition, and several ragged openings existed at its fundus, some small stones had escaped into the cavity There was a circular opening half an inch in diameter, with well defined edges, leading from the gall-bladder into the duodenum, at about three quarters of an inch below the pylorus The cystic and common ducts were patent, and one or two small stones were found in the duodenum The stomach was healthy, and there was no ulceration from the gall-bladder into it The rest of the abdominal organs were healthy The total number of stones vomited weighed 170 grains, those passed per rectum 103 grains The case is considered by Dr Pope to be excessively interesting, as showing that a gall stone may enter the duodenum and then pass backwards into the stomach

A new system for ventilation which is coming rapidly into vogue is the D C Green system The principle of the invention is the bringing of a small stream of compressed air to bear at any point of a large tube by means of an automatic nozzle, the compressed air forcing out the nozzle, according to the degree of pressure, and thus liberating itself in an annular current at the base of the cone This current is about 3 per cent of the air contained in the tube or chamber in which it escapes, but it induces a strong current of the remaining 97 per cent fed from the external atmosphere, so that a strong breeze is made to pass through the tube within which the nozzle is fixed Exhausting nozzles are used as well as injecting ones, so that while fresh air is supplied foul air can be removed As no fans or large pipes are required, the system seems especially applicable to vessels and mines, because the compressed air can be taken any distance and set free where ever the nozzle is placed

Mr W A Meredith at the recent meeting of the London Obstetrical Society, reported an interesting case of hæmatometra associated with a degenerating fibro-myoma, which he had treated by supra-vaginal hysterectomy The patient, aged 46, had for some years been subject to a large abdominal tumor, and severe menorrhagia In 1883 she was seized with pleurisy and confined to bed for eight weeks, since when menstruation had ceased She had continual abdominal tenderness and spasmodic pains in the tumor until the latter part of last year, when she entered the Samaritan Hospital The abdomen was then occupied by an enormous semi solid growth The vaginal portion of the cervix uteri was soft, but unenlarged, and its canal occluded The tumor consisted of an enormously distended uterus with a degenerating fibroid in its anterior wall, in which was a cavity communicating by a large oval aperture with the uterine cavity, both were filled with altered blood The entire mass weighed 15lbs, and probably contained originally at least 5lbs of blood Mr Meredith considered that sudden occlusion of the cervical canal, probably due to inflammatory action, caused the sudden and persistent retention, rendered permanent by partial rotation of the elongated uterine cervix during the patient's confinement in bed in 1883

Sir Risdon Bennett, M D, has published a small work entitled, "The Diseases of the Bible" In the briefly interesting and instructive little book Sir Risdon naturally travels over some rather dangerous, or at least contentious ground In the introduction the author at once directs attention to the fact that the Bible, although dealing largely with methods and suggestions for the prevention of disease, really says very little indeed respecting remedial treatment, when once any ailment has distinctly manifested itself To the precautions inculcated of old for the benefit of the Israelite we are even now indebted, according to Sir Risdon Bennett On this head he says "Sanitary laws are laid down in the most specific and detailed form, and the Mosaic sanitary code may be said to constitute the basis of modern sanitary legislation Rules relating to food, clothing, personal cleanliness, intercourse with the sick and contact with the dead, and various matters connected with social life, are given in minute detail, the value and import of which, for the most part, it is easy to see"

Dr Stephen Mackenzie says that in doses of one half grain Indian hemp, night and morning, and continued for some time, is the most valuable remedy he has met with in the treatment of persistent headache

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Sphygmograph—Chronic Progressive Caries of the Bones of the Foot—Analgesic Value of Recent Antipyretics—Dressing for "Green-stick" Fractures of the Clavicle

The fifth special meeting of the Fifth District Branch of the New York State Medical Association was held at the Pavilion Hotel, New Brighton, Staten Island, on the 15th of November, and was one of the most successful of the series that have been held from time to time during the past three years The

papers presented were excellent, and the discussions of the various subjects brought forward in them of more than ordinary interest, while from a social point of view the occasion was a most attractive one It is the aim of these meetings to bring together in pleasant intercourse members of the profession from different parts of the District, and all the arrangements for the one in question were of the most satisfactory character, a result due to the exertions of the committee having the matter in hand, which consisted of Drs F U Johnson, Alfred L Carroll, and W C Walser, of Staten Island

The scientific proceedings were opened by Dr Carroll, who in his lucid and finished style made a forcible plea for the more general employment of the sphygmograph, pointing out the causes why the results hitherto obtained with it were often so unsatisfactory His remarks, which were on the clinical significance of sphygmographic tracings, were illustrated by a large number of examples, and among them were two from patients suffering with exophthalmic goitre, the tracings from which, so far as he was aware, had never before been taken

While the sphygmograph, he said, could never supersede the trained ear of the auscultator in cardiac disorders, it might guide his examinations, and perhaps modify his prognosis, and, in addition, in some instances, it might serve to localize an internal aneurism with a precision unattainable by any other means It was well known that the intensity of a murmur at one of the valvular orifices was not invariably proportionate to the gravity of the lesion which induced it, and, except where the attending circumstances of aggravated cases aided our judgment, we were often uncertain as to the exact condition present Here the sphygmograph might come to our relief with a mechanical measurement more accurate than our unassisted senses Variations of muscular tension inappreciable by the most delicate and practiced touch, degrees of obstruction or regurgitation otherwise unascertainable, were graphically recorded

Too much, however, ought not to be expected from the sphygmograph Its tracings in a given form of disease were not identical and diacritic, they were only generically similar It was not to be considered as a means of diagnosis but, like other so called "instruments of precision," as a frequently useful aid to diagnosis Some years ago, in a paper published in the *New York Medical Journal*, he had endeavored to point out the extent and limitations of its utility, his present purpose was chiefly to call attention to a hitherto unnoticed source of misconception in regard to its registrations

One of the principal drawbacks to the general recognition of the value of the sphygmograph was the very ingenuity expended in its improvement, which had resulted in the invention and adoption of several different patterns of mechanism, each of which gave a tracing differing somewhat from those of the others with the same pulse Hence, since the significance of every part of the hieroglyph depended on its conformity with or departure from a known normal standard, it was necessary for the more recondite indications of any sphygmogram to be told by what instrument it had been taken, and without this information, and knowledge of the normal performance of the particular pattern of instrument employed, it was impossible to compare the results of different observations and to profit by published records Having referred to the differences in the different varieties of sphygmographs, some of which he exhibited, Dr Carroll stated that the rate of speed at which the slip was made to move would also materially modify the sphygmogram

In view of these facts, and to establish sphygmography in the professional estimation which it merited, he said, in conclusion, that it was desirable—since it was not likely that any standard would be universally adopted—that all who published records of their work should not only mention the instrument which they employed, but give in addition, for comparison, its tracing of a normal pulse

Dr Walser, of Port Richmond, read a paper on "Chronic Progressive Caries of the Bones of the Foot, with Cases and Presentation of a Patient" The two cases referred to were of extreme interest and rarity In one of them, a female, the trouble had commenced at the age of 10 months, and in the other, the patient presented, who was a male, at the age of 22 years In both instances the origin of the trouble was very obscure, there being no syphilitic or other diathetic history The disease was comparatively painless, in the case of the woman, in which it did not extend beyond the feet, completely so In the man who was presented it also involved the tibia, and the only pain that he complained of was referred to that region

Dr S H Benton, of Brooklyn, made a valuable contribution to the subject of the analgesic efficiency of the recent antipyretics He said that his attention was first drawn to the anodyne properties of antipyrin in November, 1886, when he found that this agent, given in a temporary febrile condition, relieved headache in a case of two years' standing, in which a very large number of remedies had been tried in vain After three months of treatment by antipyrin, given when indicated for pain, the headache, which was located in the right mastoid region, permanently disappeared Soon afterwards Dr Benton tried antipyrin with excellent results in the case of his own wife She was suffering from an attack of hemicrania, accompanied with a severe brachial neuralgia, with which she had frequently been troubled during the past three or four years Since then Dr Benton had several times repeated the antipyrin in similar attacks, and always successfully While he could not say that she had been permanently relieved, it was a fact that the interval between the attacks had become much longer than formerly, and she had not complained of the pain in the brachial plexus for two months

Having related a case of locomotor ataxia in which antipyrin gave much relief, he said that he was not sure that one would be justified in continuing the administration of such agents for an indefinite period, as would doubtless be necessary in the pains of locomotor ataxia It was said, he continued, that the action of antifebrin and its analogues has a destruc-

of performing Alexander's operation, and an operation for shortening the sacro-uterine ligaments Not all will agree with the recommendation to treat pelvic abscess through the rectum, nor to separate adhesions of the retroverted uterus through an incision in the cul-de-sac, yet in this age of innovation and rapid advance in surgery, new procedures must not be too hastily condemned

To the many members of the medical profession throughout the country who are well acquainted with the ability, the knowledge and energy of Byford the younger, it will be a genuine pleasure to see his name on the title page as co-editor of the present edition

The book, in brief, is a text book for the student, a guide to the practitioner, a counselor to the specialist, and an honor to the gynecological literature of America

A THEORETICAL AND PRACTICAL TREATISE ON ASTIGMATISM By SWAN M BURNETT, M D, Professor of Ophthalmology and Otology in the University of Georgetown, Ophthalmic and Aural Surgeon to the Garfield Hospital, and Director of the Ophthalmic and Aural Clinic at the Central Dispensary and Emergency Hospital, Washington, D C With 59 diagrams and illustrations 8vo, pp 245. St Louis J H Chambers & Co 1887

This work is the only one of its kind It is devoted entirely to the study of the nature and correction of astigmatism The subject is an important one not only to specialists but also to the general practitioner The relation between so called nervous diseases and errors of refraction has become generally recognized Reflex annoyances dependent upon ametropia are daily observed, and the attention of physicians cannot be too forcibly drawn to the important role played by optical defects in the causation of these neuroses The author has defined the fundamental principles necessary for a proper understanding of astigmatism, in a clear and concise manner, all the facts are treated in a popular style, enabling the student to grasp readily a subject usually considered difficult In the chapter on the use of atropine for the detection of errors of refraction, the doctor emphasizes an opinion that latent hypermetropia of a low degree should not be considered abnormal, for, he says, "The result of an examination of the refraction of a large number of children ranging in age from a few hours to 10 and 12 years, seems to point to the fact that in the human eye we have from infancy to adult life a gradual evolution from the hypermetropic to the emmetropic and myopic condition" In many cases all of the hypermetropia is overcome by the natural tonicity of the ciliary muscle, which can not be regarded as pathological and interpreted as a muscular spasm All methods of examination are reviewed A special chapter is devoted to the investigation of the "shadow test," known as keratoscopy and retinoscopy, for which however the name of skiascopy (shadow test) as suggested by M Egger, is substituted An appendix containing a statistical record of 806 astigmatic eyes will undoubtedly be of great value to scientific investigators in search of reliable material

TREATISE ON DISEASES OF THE SKIN By T MCCALL ANDERSON, M D, Professor of Clinical Medicine in the University of Glasgow With colored plates and numerous wood engravings Octavo 650 pages Cloth, $4 50, Leather, $5 50 Philadelphia P Blakiston, Son & Co 1887

This is the most recently published work on the subject and is worthy of a place among the other numerous text books on dermatology The wide experience and eminent character of the author will command attention His American publisher has made a handsome volume which it will illustrate with about seventy cuts The scope of the work is the same as that of others on the subject Particular attention is given to the discussion of diagnosis and treatment It is a noteworthy fact that Dr Anderson is not a specialist but a general practitioner He has had, however, unusual opportunity for the study of diseases of the skin 11,000 consecutive cases of various skin diseases are analyzed by the author Considerable space is devoted to diseases of the hairs Among other things we notice that in the healing of deep ulcers the author does not recommend sponge grafting which has been introduced by his fellow countryman Dr Hamilton, but thinks that such grafts often rather delay and retard healing

MISCELLANEOUS.

THE NORTH CENTRAL ILLINOIS MEDICAL ASSOCIATION, will hold its fourteenth annual meeting in the City Hall, at Streator, Tuesday, December 6, 1887, beginning at 10 30 A M

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM NOVEMBER 19 1887, TO NOVEMBER 25 1887

Col Glover Perin, Asst Surgeon General, retired from active service November 17 1887, by operation of law S O 268, A G O, November 17, 1887

Col A K Smith, Surgeon, assigned to duty as attending surgeon in New York City

Lt Col J R Smith, Surgeon, ordered for duty as Medical Director, Dept of Dakota

Major S M Horton, Surgeon, granted six months' leave of absence, on surgeon's certificate of disability

Capt W H Arthur, Asst Surgeon, granted two months' leave of absence, with permission to apply for two months' extension, to take effect on the arrival at Ft Niagara, N Y, of Asst Surgeon Paul R Brown

First Lieut J R Kean, Asst Surgeon, granted two months' leave of absence to take effect about December 1 S O 269, A G O, November 18, 1887

Capt Paul R Brown, Asst Surgeon, ordered to Ft Niagara, N Y

Capt John O Skinner, Asst Surgeon, ordered to Ft Ontario, N Y

Capt Chas Richard, Asst Surgeon, ordered to post near Denver, Col

Capt E C Carter, Asst Surgeon, ordered to Willet's Point, N Y S O 270, A G O, November 19 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING NOVEMBER 26, 1887

P A Surgeon F S Nash, detached from duty at the Smithsonian Institute, and ordered to the Washington Navy Yard.

ADDRESSES.

ADDRESS TO THE MEMBERS OF THE REGULAR MEDICAL PROFESSION OF LOUISIANA

BY JOSEPH JONES, M D,

PRESIDENT OF THE LOUISIANA STATE MEDICAL SOCIETY

GENTLEMEN —The tenth annual session of the Louisiana State Medical Society will be held in the town of Monroe on the third Wednesday in April, 1888, and subjects of paramount importance to the Medical Profession will be presented for consideration and discussion We briefly formulate some of the questions now at issue, with the hope that they may receive the earnest consideration of the medical profession

I —THE ESTABLISHMENT OF A STATE MEDICAL LIBRARY,

for the preservation of the archives of the Society, the diffusion of medical knowledge, and the promotion of original scientific research in all the departments of medical science

The object sought to be accomplished is the collection, classification and preservation of the manuscripts, documents and publications bearing upon the eventful history of the medical profession of the Mississippi Valley from the first settlement of Louisiana in 1699 to the present day

Every fact, document or publication that relates to the history of epidemics, and to the origin, cause and prevention of endemic and epidemic diseases in Louisiana and in the Mississippi Valley, should be carefully preserved in permanent form, and in a permanent building, and this building should also serve the purpose of a Central Hall, for the meetings of the State Medical Society at stated periods It is believed that facts of great value, and rare documents and works, are scattered over this land, which if gathered together and sheltered within the ample folds of a permanent building, would prove of inestimable value

It is the earnest hope of the patriot and friend of progress that each member of the Louisiana State Medical Society and of the entire medical profession of the South and Southwest, will view with favor this important enterprise, and contribute documents, works, original researches, and practical observations for permanent preservation in the medical archives

We cannot build and maintain a library without money Without the generous response of the medical profession this useful and benevolent project will remain unaccomplished

Dr J S Johnston, of Alexandria, by his generous gift, during the meeting of the Louisiana State Medical Society on the 12th of April, 1887, of a square of ground for the building of the library, has set a noble example to the medical profession

II —MEDICAL EDUCATION

When we consider the importance and elevated character of the science of medicine—its object, the preservation of the health and lives, and the healing of the diseases, and the amelioration of the physical and mental sufferings of our fellow human beings—its extent embracing a knowledge of all science—it is evident that medical education should engage the earnest attention of the entire medical profession The advances made in all the branches of knowledge, and especially in the science of medicine, during the past century, have exceeded in extent and value those of all past ages, and it is no longer possible to compress its vast domain within the narrow limits of *seven Professorships*, or to compress its circle within the brief span of less than thirty months

The present age owes its wonderful progress to *experimental scientific research*

The value and perfection of modern educational systems are due, to a large extent, to practical demonstrations in the great field of physics, chemistry, physiology, pathology, therapeutics, and clinical medicine

Universities of learning and science must be regarded as composed of two distinct bodies On the one hand must be ranged the organizing powers and executive officers—the *Trustees* and *Professors*, and on the other, the greater and more useful body, the grand army of the *Alumni* The voice of the latter should not be silent, but should speak in thunder tones, demanding a firm, wise and steady enlargement and practical advance of the colleges and universities all along the lines of literature, art, and science

III —PUBLIC AND INTERNATIONAL HYGIENE

The medical profession of Louisiana should be foremost in the great work of perfecting and unifying the health and quarantine laws of the individual States and Territories of this great Republic The confusion, alarm and terror of the inhabitants of entire communities and States, following local outbreaks of yellow fever on the Atlantic and Gulf

Coasts, and the threatened importation of cholera from Europe, reveal an imperfection of sanitary laws and knowledge, and of defencelessness against invasions of foreign pestilence This condition of the disorganized sanitary forces of the United States, can only be fitly compared with her dismantled fortresses and rotten navy

It is high time that the medical profession and the civil authorities of the individual States and Territories should be aroused to the necessity and importance of united action for the discussion, perfection and inauguration of comprehensive measures for the exclusion of foreign, and the eradication of domestic, pestilence This unification and perfection of the sanitary and quarantine laws of this Nation can be effected, not by the combined wisdom and action of the legal representatives of the sovereign States, acting in concert and assembled in general convention Let the accomplished, learned and patriotic physicians of Louisiana take the lead in this work, which has for its aim the preservation of the lives of the people, and the advancement of the material social and moral welfare of our country

IV —PUBLIC SCHOOLS, THEIR HYGIENE, AND THE INTRODUCTION OF THE STUDY OF CHEMISTRY

The first duty of the managers and officials of the public schools of Louisiana, should be to perfect their hygienic arrangements, which in many localities are proven to be defective and detrimental to the health of the teachers and pupils The science of chemistry has contributed more to the physical and industrial progress and wealth of the human race than all other branches of human knowledge Chemistry is the basis of hygiene and physiology, and it has furnished facts of inestimable value to the agriculturist, to the mining engineer, and to the manufacturing chemist

The introduction of the study of inorganic and organic chemistry into the public schools of Louisiana, will not only aid in the intellectual training of the children, but will aid materially in the agricultural and mineral progress and development of the State

V—The Hygiene, Diseases and Treatment of Prisoners in the penitentiary, prisons and jails of Louisiana

VI—The establishment of a School for the Education and Training of Nurses, and the consideration of the means by which the nurses employed in the Charity Hospitals of New Orleans and of other cities may receive regular and just compensation for their services

VII—The revision, amendment, perfection, and re enactment of the acts of the General Assembly of Louisiana relative to the Practice of Medicine in Louisiana

In this connection, the protection of the public against unqualified and unprincipled practitioners of medicine and pharmacy, and against the irresponsible and indiscreet sale of alcoholic liquors, drugs and poisons by druggists, should receive careful consideration, with a view of influencing legislative action

VIII —ORGANIZATION

Of the 992 registered physicians in the State of Louisiana, up to January 1, 1887, 773 are classed as regular, and of this number only 176 are members of Louisiana State Medical Association Of the fifty nine Parishes of Louisiana thirty-four, or a little over one half, have representatives in the State Medical Society

These figures furnish an argument for renewed activity on the part of the members of the parent organization, to secure the organization of Parish Medical Societies The members of the medical profession throughout the State are most earnestly and respectfully urged to organize societies and send delegates to the meeting in Monroe

IX —ORIGINAL CONTRIBUTIONS TO MEDICAL SCIENCE

The value of the transactions of medical societies depends primarily and almost exclusively upon the contributions of their members to the various branches of medical science It is earnestly hoped that the Transactions of 1888 will be enriched by the carefully recorded experience of the physicians of Louisiana, relating to general medicine, general surgery, obstetrics, gynecology, therapeutics, materia medica, anatomy, physiology, pathology, diseases of children, ophthalmology, dermatology, hygiene, climatology, diseases of the nervous system, dental and oral surgery

No State offers a richer or wider field for the careful and comprehensive study of disease, its chief city, situated at the mouth of the most important river in the world, offers, in its Charity Hospital, a vast field for clinical study in all the branches of medicine and surgery, its Delta has furnished, and still furnishes, the most important area for the study of the relations of climate and soil to the development and propagation of all the various forms of malarial disease Here yellow fever has committed its greatest ravages, and here it has received the careful study of learned and humane physicians Every fact relating to the history, origin, propagation and treatment of yellow fever and Asiatic cholera, typhus and typhoid fevers, malarial hæmorrhage, Oriental leprosy, hydrophobia, scarlet fever, diphtheria, and other endemic infectious and epidemic diseases, in the different parishes, cities, towns and villages of this State, should be recorded by the practicing physicians, and presented in the form of cases, essays, and monographs, for publication and permanent preservation in the archives of the State Society.

COMMITTEE ON ESSAYS

The committee on essays as now constituted consists of the following members Dr I J Newton, Bastrop, Chairman, Drs R H Day, Baton Rouge, J W Dupree, Baton Rouge, H D Bruns, New Orleans, C D Owens, Alexandria, W D White, Abbeville, Smith Gordon, Alexandria, W L Dickson, New Orleans, R W Seay, Pilcher's Point, Thomas Hebert, New Iberia

The physicians of Louisiana are respectfully requested to forward the titles of their essays, monographs, papers, and cases, at the earliest practicable

moment, to the accomplished and energetic chairman, or to any one of the eminent medical men composing the committee on essays

In the past much good has been accomplished by the labors of the chairman of this committee, and its members have demonstrated their devotion to the best interests of our profession by their valuable contributions to its literature

[136 Washington Avenue, 4th District, New Orleans, La., November, 1887

ORIGINAL ARTICLES.

THE CAUSE AND TREATMENT OF INFANTILE ECZEMA

Read in the Section on Diseases of Women and Children, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY JOHN V SHOEMAKER, A M, M D,
OF PHILADELPHIA PA

Infantile eczema is one of the most common diseases of early life It is always a distressing and frequently an obstinate affection, remaining for weeks or months, but as a rule, it is much more amenable to treatment than the eczema of adults It may occur at a period during infancy, but it is most frequently observed during the first six months of infantile life, at the time of weaning, and during the process of dentition

It may appear in a variety of forms In some cases it is characterized by the development of a variable number of erythematous spots, or blotches upon the face, scalp, and other portions of the body In others the eruption is purely papular, in still others it consists solely of vesicles situated upon a reddened inflamed base, or both lesions may be intermingled The pustular variety is characterized by the formation of pustules of various sizes, either alone or commingled with vesicles, papules and vesico papules The disease may involve any or all portions of the integument, but it most frequently attacks the face, scalp, neck, chest, buttocks, and the upper and lower extremities It pursues a variable course The papular and erythematous forms usually disappear by resolution, but they may pass imperceptibly into the chronic squamous stage of the disease The surface then presents a dull red infiltrated appearance, and is covered with a number of minute epidermic scales

The vesicular and pustular varieties rarely terminate in resolution As a rule, the vesicles and pustules burst within a few days after their development, exposing a raw weeping, bleeding surface, from which a sero purulent fluid exudes, and dries into large firm yellowish crusts When the scalp is the seat of the eruption, the hairs are matted together by the exudation, and the entire scalp becomes covered with yellowish masses, forming the condition known as crustalactea As the disease progresses the irritation increases, so that the inclination to scratch the parts become almost irresistible, and patients tear the surface with their fingernails even while asleep This, of course, increases the exudation and enlarges the diseased area After an interval of several weeks the morbid action may cease, spontaneous repair take place, and the crusts drop off, disclosing a healthy but somewhat reddened surface Usually, however, unless appropriate treatment be instituted the disease passes into the chronic stage, and remains for months or years with occasional periods of amelioration and exacerbation

Infantile eczema is due practically to one of four causes 1 Insufficient or improper food 2 Imperfect assimilation 3 Deficient excretion 4 External irritation

Insufficient or Improper Food—This is one of the most frequent exciting causes of the disease If the mother's milk is scanty in quantity, or poor in quality, or altered in character by pregnancy, passion, menstruation, anxiety or disease, the nutrition of the child will suffer, and eczematous or other eruptions speedily appear If the child is handfed, and given unsuitable and indigestible articles of food, or, if the cow's milk upon which it is nourished is so diluted with water as to be deprived of its value the same result will follow

Imperfect Assimilation—This is another potent factor in the production of the disease The food may be perfect in all respects, but if owing to disturbances of the digestive tract a considerable portion of it is either rejected by vomiting, or hurried out through the intestinal canal before digestion, and assimilation are complete, the blood will become thin, the nervous system will suffer, and various cutaneous eruptions appear

Deficient Excretion—Deficient excretion is not as frequently chargeable with the development of infantile eczema, as it is with many other cutaneous disorders, but many stubborn cases spontaneously disappear when the normal functions of the various excretory organs are reestablished

External Irritation—This is frequently the unsuspected cause of numerous cases of infantile eczema Among the common sources of irritation may be mentioned, woollen or flannel clothing, light clothing, dyed clothing, wet diapers, scratching, and the too frequent washing of the body and scalp with soap and water The eruption is often aggravated by the use of quack preparations, or ointments recommended by obliging friends and neighbors

Treatment—The general principles upon which the successful treatment of infantile eczema must be based, are, to improve the nutrition of the patient, correct any disorder of digestion or excretion that may exist, and protect the affected surface from further irritation and endeavor to restore it to its normal condition The measures to be employed in each case will vary with the cause of the disease, and the extent, variety and stage of the eruption In some cases attention to diet and hygiene will be sufficient to effect a cure In other cases local or constitutional medication will be required, while in obstinate cases both local and constitutional remedies must be employed In mild cases of the erythematous or papular variety, in which the deficient character of the food supply is plainly appar-

ent, immediate improvement can often be obtained by simply giving a sufficient quantity of appropriate nourishment There are several ways of accomplishing this If the mother is nursing the child, and her milk is scanty or impoverished, she should be placed upon tonics and a liberal diet, and directed to give the child a definite quantity of cow's milk in addition to her own at stated intervals throughout the day I have notes of several cases in which a rapid and decided improvement in the character and amount of the mother's milk, and a disappearance of the eruption from her child followed a liberal diet, conjoined with the use of the formulæ

℞ Tinct ignatiæ gtt x
Tinct serpentariæ ℥ vj
Tinct cinchonæ ℥ j
℔ Sig Teaspoonful in water before meals and at bedtime

If, unfortunately, the infant cannot be nursed by its mother, the best substitute for its natural food is pure undiluted cow's milk, unmixed with any other substance whatever More than thirty years ago Dr N S Davis declared before this Association, that the practice of diluting the cow's milk given to infants was the direct cause of incalculable suffering and innumerable deaths Careful observation has convinced me of the truth of Dr Davis' assertion Time and again have I been called in to see infants of from ten weeks to six months old who were crying continually, pining away, and in addition were covered with various forms of eczematous eruptions On inquiring what the little patients were fed upon, answers were one part milk and three parts water, one part milk, one part flour, and five or six parts water In one case the unfortunate child was being slowly and unknowingly starved to death upon one part milk and eight parts water My orders in every case were to at once give each child plenty of pure undiluted cow's milk and nothing else for food For some I directed 2 grains of pepsin to be given in addition with each feeding No other medication was employed or required, and in every case the eruption spontaneously disappeared in from a few days to two weeks

In other cases it will be found that the trouble is due to the child being given potatoes, pies, pastry, pork and all sorts of table-food, preparatory to being weaned, or to assist it to cut its teeth The child's stomach is unable to digest such food, its gastro-intestinal canal is disordered, and various eruptions appear that are charged to dentition Dentition is a perfectly natural process, and in the overwhelming majority of cases is accomplished without any reflex or direct disturbance of the system The cases of eczema attributed to it are numerous, but they are really due to errors of feeding and disorders of digestion

Cases of infantile eczema, due to imperfect digestion and mal-assimilation, require to be studied carefully Those in which there is a deficiency in the gastric juice, are benefited by the administration with each feeding of from ½ to 2 grains of pure pepsin, or from 2 to 5 grains of lactopeptine Nux vomica in doses of from one quarter to two minims of the tincture three times a day is also valuable Minute doses of the chloride of iron, or of hydrochloric acid, sometimes yield better results than either pepsin or nux vomica If diarrhœa exist, small doses of opium or Dover's powders, with an astringent tonic, like cinchona or geranium, will be of the utmost value In some cases a change of air, as to the seashore or the mountains, will be the most effective remedy Cod-liver oil will be found of especial value in all patient's that are debilitated, anæmic, or that present any evidences of the scrofulous diathesis It may be given in half drachm doses three times a day, or used as an inunction every morning In many cases, no other treatment will be necessary The syrup of the iodide of iron is also valuable The dose will vary from five to twenty drops, according to the age of the patient It may be given in any convenient medium or in combination with cod liver oil

Quinine is also an effective remedy, especially in malarious districts and in cases in which the eruption manifests itself during the spring and autumn months It may be given in the syrup of yerba santa, in doses of from ½ grain to 3 grains once or twice a day Very often in cases arising from gastro-intestinal irritation or complicated by constipation, marked and rapid improvement can be obtained from the use of minute doses of calomel, alone or combined with a small quantity of jalap resin

℞ Hydrarg chlor mitis gr j
Resinæ jalapæ grs j
Sacchari albæ grs x
℔ Make 6 powders
Sig One powder every other day

Podophyllin and leptandrin will also be found serviceable Castor-oil is a time-honored and an effective remedy Small doses of syrup of rhubarb or carbonate of magnesia are frequently beneficial In acute cases accompanied by fever and an increase of the circulation, aconite is potent for good It will be noticed that I have said nothing as to the use of arsenic in the treatment of the various forms of infantile eczema The omission was intentional Arsenic is sometimes requisite in the treatment of obstinate forms of eczema in adults, but in the eczema of childhood it is not only unnecessary, but frequently injurious For many years I have not employed arsenic in cases of infantile eczema which have come under my observation I would advise that arsenic be avoided in the treatment of infantile eczema, as its use is often productive of more injury than any benefit it may produce on the disease

Local Treatment—In cases in which the itching is a marked symptom, various soothing and anti pruritic lotions and ointments may be employed Those which I most frequently order are

℞ Acidi carbolici grs ij
Hydrarg chlor mitis gr x
Ung tinci oxide benz ℥j
℔ Ft ungt

℞ Creasoti m iij
Aquæ ℥iij
℔ Ft loto

℞ Chloral hydrat gr v
Aquæ menth pip ℥ij
℔ Ft loto

Applications of cold water, ice water, lead water and laudanum, or a saturated solution of bicarbonate of soda, will also be found grateful and calmative

When the eruption has become subacute or chronic, and the integument is covered with crusts, it would be folly to expect any improvement until the diseased surface is exposed to view The affected region should be covered with a starch poultice, or saturated with oil to loosen the crusts and scales, which must be carefully picked off Various stimulating ointments may then be applied to the exposed, denuded surface, but care must be taken to avoid increasing the irritation and inflammation The medicaments employed should be such as will constringe the capillaries and reduce the congestion, while they at the same time form a protective covering for the raw and oozing corium The subnitrate and the oleate of bismuth and the oleate of zinc, either in powder or ointment form, are excellent applications for this purpose The ordinary benzoated oxide of zinc ointment alone, with 5 grains of camphor to the ounce, is also serviceable The following ointment will be found valuable

℞	Pulv opii	gr iij
	Acidi tannici	ʒss
	Plumbi carbonatis	ʒj
	Olei anthemidis	gtt v
	Adipis	ʒj

Another excellent procedure is to brush a 25 per cent solution of the fluid extract of geranium over the surface after the scales have been removed Diachylon ointment, weak tar ointment, cucumber ointment, weak salicylic acid ointment, and the ointment of the carbonate of lead, may also be employed with benefit Harsh and irritating applications must be sedulously avoided, as they are certain to protract the disease Cases due to external irritation usually require nothing more than the removal of the irritant and the application of a soothing ointment or lotion to the part affected Tight, dyed, woolen or flannel clothing should be replaced by articles of wear composed of some less offending material If wet diapers are at fault they should be removed as soon as soiled, the parts gently mopped dry with a soft cloth, and then dusted with zinc oxide, bismuth subnitrate, or lead carbonate, or painted with a dilute solution of geranium maculatum If the eruption is due to the scratching and irritation consequent upon the presence of lice, the hair should be cut short, and any of the following ointments rubbed well into the scalp

℞	Hydrarg chlor mitis	gr x
	Acidi carbolici	gr ij
	Ungt zinci oxidi	ʒj
℞	Naphthithol	gr x
	Ung zinci oxidi	ʒj
℞	Sulphuris sublimati	ʒij
	Pulv marantæ	ʒij
	Ungt aquæ rosæ	ʒj

Cases that are the result of the too free use of soap and water will usually spontaneously subside upon the suspension of the practice An infant's body should be bathed every day in tepid or warm water, but soap should not be applied to its delicate skin more than two or three times a week

TWO CASES OF TUMOR OF THE OPTIC NERVE

Read in the Section on Ophthalmology and Otology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY GEO E FROTHINGHAM, M D,

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MICHIGAN

Forty-three cases of tumor of the optic nerve have been reported, of which a large proportion have been sarcomata Fibromata stand next in order of frequency Scirrhous carcinoma and genuine neuroma have also been reported [1] I have met two cases in my own practice, both of which were sarcomata The following is a brief report of these cases [The tumors were presented for examination]

Case 1 —C A H, a lad æt 7 years, residing in East Saginaw, Mich, was brought to me for consultation May 18, 1882 The father gave the following history About a month previous he noticed that the right eye seemed larger, and that it was totally blind It had not changed in appearance since the deformity was first noticed He consulted an oculist, who was in doubt as to the condition The boy had experienced but very little pain in the affected eye, and was free from headache

I found the right eye totally blind and affected with slight exophthalmus Tension normal Left eye appeared normal, V = $\frac{20}{20}$, Hm = o 75 D Ophthalmoscopic examination showed the disc of right eye elevated and outline indistinct The elevation of the disc was estimated as equal to about 1¾ mm The lymphatic glands of the neck were enlarged, and the patient had the appearance of being affected with scrofula No tumor could be felt on passing the finger into the orbit as far as practicable The walls of the orbit seemed smooth, the eyeball being displaced about 3 mm directly forward, its movements being unrestricted From appearances I thought a tumor existed surrounding the optic nerve, but of what character could not be determined The exophthalmus might be due to other changes deep in the orbit If a tumor existed, the question arose as to whether it was malignant The question also arose as to whether the enlarged lymphatics were due to scrofula, or were they evidence of malignant disease? I prescribed iodide of potassium and citrate of iron and ammonia, and requested that the patient be brought to me again in two weeks

June 13, patient returned, feeling much better, appetite improved, and the enlargement of the lymphatics was much less The outline of the right optic disc is less obscured, but the elevation of the papilla seemed about the same I directed a continuation of the iodide and iron and added cod liver oil and a bitter tonic to the medication September 16, patient returned Has discontinued medication since July 10 The optic papilla seemed more elevated, but the exophthalmus remained about the same I advised a return to the previous medication, but after a few weeks, to substitute the syrup of iodide of iron in suitable doses for the iodide of potassium and citrate of iron and ammonium

[1] Vossius Archives of Ophthal, vol xii p 294 also vol xv p 133

From this time to January 13, 1883, the eye remained about the same It then began to project a little more The same general plan of treatment was continued, as no operative procedure seemed to be called for The tumor continued to grow from this time rapidly, and on July 21, an examination detected a smooth, somewhat yielding tumor on pressing the finger into the orbit beside the eyeball It seemed to be in the pyramidal space, inclosed by the recti muscles, but its exact nature could not be determined Another examination was requested at an early date This was, however, delayed until September 1, when the patient was brought to me just as I was about to depart on a journey The tumor had grown even more rapidly than before, and the exophthalmus was extreme The general health was good, and the enlargement of the glands in the neck had about disappeared I advised immediate operation, but it was decided to defer it until my return, which was expected in two weeks This was unavoidably delayed, and it was not until September 27 that the operation was performed

The patient being etherized, an incision was made through the conjunctiva and fascia, and the tendon of the internal rectus divided close to its attachment to the globe The wound being enlarged above and below, the finger was introduced, and a large tumor, involving the nerve, was found to exist, and extending deep into the orbit The conjunctiva, fascia and tendons were then all divided as in enucleation, and the eyeball drawn outward The nature of the tumor now became apparent It was of large size, conical in shape, and involved the optic nerve, extending from its insertion into the globe backward into the optic foramen With blunt strabismus hook, and other instruments, the tumor was carefully separated from its attachments, and forcibly drawn forward and divided with curved, probe-pointed scissors, as far back as possible The wound was dressed as after an ordinary enucleation The patient made a rapid recovery, with no complications whatever

There was a fair stump for an artificial eye, which was fitted after some months, as he would not allow one to be fitted sooner Fearing a return of the growth, several subsequent examinations were made, but no enlargements reappeared anywhere in the orbit On April 26, 1887, I received a letter from the father in response to one I wrote to him inquiring as to the present condition of the patient He stated that there had been no further trouble, no tumor having reappeared in the orbit, and that the boy was in good health, and had no trouble in wearing his artificial eye He was nervous and fretful by spells, but was progressing well in his studies, and was active in the usual sports of boys of his age There was still some slight enlargement of the glands of the neck As yet there is certainly no indication of intracranial development of the tumor The other eye remains perfect

From the appearance of the tumor I feared that it already involved the intracranial portion of the nerve, and that it was malignant in character The cut end did not look like normal nerve tissue, but was swollen and softened I gave a guarded prognosis as to the final outcome The very rapid growth during the last few months added to the suspicion of malignancy An examination of the tumor showed that it involved the entire substance of the optic nerve, from its entrance into the bulb as far back as the optic foramen It was about $1\frac{5}{8}$ inch in its longitudinal diameter, and about $1\frac{1}{8}$ inch in its transverse diameter In structure it is a round-celled sarcoma

Case 2 —Miss M W, æt 19, Grand Rapids, Mich, entered my clinic April 4, 1885, giving the following history In May, 1884, she had an attack of frontal headache, accompanied by vertigo and a dull, heavy feeling over both eyes, with a slight pain in the left orbit These symptoms subsided in a few days, except a slight dull pain in the left eye, which has continued up to the present time Some time after this, sight in the left eye commenced to fail gradually, and the eye appeared to bulge slightly This exophthalmus has continued to increase very slowly She could still read coarse print with this eye The vision of the right eye was $\frac{20}{20}$ The ophthalmoscope showed no abnormal appearance of the fundus, the disc showing no change that could be decided as pathological The movement of the eyeball was unimpaired and the protrusion was slight and directly forward The diagnosis was that a tumor probably existed, lying close upon and perhaps involving the optic nerve As useful vision remained, and as there was no rapid growth of the tumor indicating malignancy, the patient was advised to wait until the size of the tumor, rapid growth, or some other condition should call for or warrant an operation for the removal of the growth As useful vision existed, and as there was no prospect of removing the tumor without sacrificing the eye, I did not think operative interference then admissible The patient agreed to return if sight became obliterated and the tumor became more painful, or increased much or rapidly in size

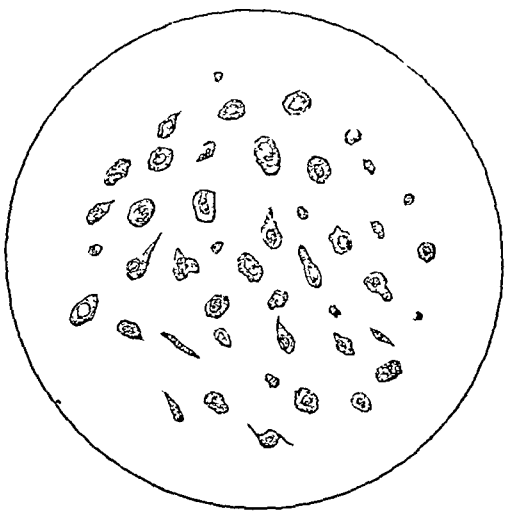
On March 30, 1886, the patient again entered the hospital, stating that there had been but little change in the eye until about two weeks before her return The sight of the eye then rapidly failed, and the eyeball became very prominent The bulging had from that time rapidly increased until the exophthalmus had reached an extreme degree The bulging was directly forward and the motion of the eyeball unimpaired There was a constant dull pain in the eye My diagnosis was a tumor, probably of the optic nerve An immediate operation was advised

On April 3, the patient was etherized and the operation performed with careful antiseptic precautions After a preliminary incision and division of the external rectus, and extending the outer canthus, an exploration was made and the tumor was found to involve the optic nerve I decided not to attempt to save the eyeball but to remove it, together with the tumor Subsequent events proved this to be the wisest course The operation was completed by carefully separating the eyeball and tumor from their connections, drawing the tumor well forward and cutting it off as far back as possible

The wound was then treated as after ordinary enu-

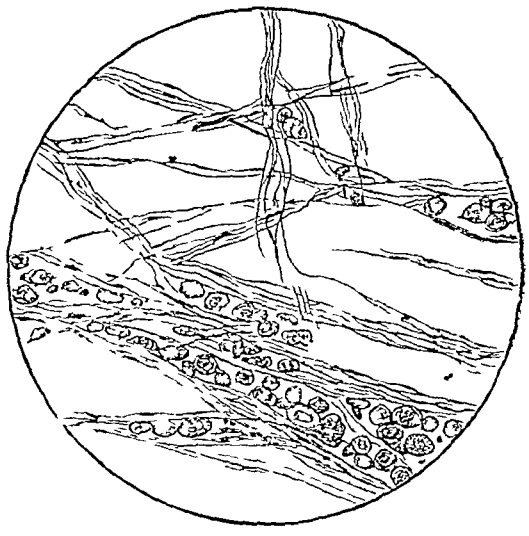
cleation Notwithstanding the antiseptic precautions, severe erysipelatous inflammation supervened, and there were symptoms also of meningitis There was severe headache, and the temperature remained at 103° for nearly two days On the fourth day after the operation the temperature fell to 101°, and in a few days fell to normal There was sloughing of cellular tissue, which on the fourteenth day after the operation had entirely separated, and the swelling had subsided A cavity was thus left that extended to the bottom of the orbit and allowed inspection of the optic foramen, which showed as a depressed surface, with no indication of a return of the growth This opening gradually closed, but led to such deformity and shrinkage of the stump that no attempt was made to fit an artificial eye An examination of the tumor showed it to involve the optic nerve from a point commencing about half an inch back of the eyeball and extending from that point back into the optic foramen The tumor itself was a little more than 1½ inch long and a little more than an inch in its transverse diameter A microscopic examination showed the tumor to be a round celled sarcoma like that found in *Case 1*

The following drawings, prepared by Prof C H Stowell, who kindly made the microscopic examina-



Free Cells from soft portions of Tumor

tions for me, represent the character of the growth. Prof Stowell makes the following report of the result of his examinations of the tumors "An examination of the tumors you gave me, and labeled Nos 1 and 2, results as follows Both growths are of the same structure An examination of the cellular elements shows a vast number of small, round, nucleated cells, with a few spindle shaped cells Sections of these tumors show a stroma of delicate connective tissue For the most part this framework is quite scanty, in one of the growths, near the periphery, it is quite firm and dense In this delicate fibrillar framework, there is a more or less granular intercellular substance Both of these growths represent a *round celled sarcoma* Considering their location, however, they might be classed with the '*gliomata*' of Virchow As I fail to find evidences of myxomata, and as the sarcomata are so marked, each might properly be called a *sarco glioma* "



Stroma and Cells, from denser portions of Tumor

In reply to my letter of inquiry the patient wrote, on the 18th ultimo, that there has never been any pain since her recovery from the operation There has been no return of the tumor within the orbit, and she is perfectly well

Sarcomatous tumors involving other structures of the orbit, excepting when within the eyeball itself, are, in my experience, very liable to recur, especially in children, even when completely extirpated When not completely removed, the operation seems to stimulate the growth

In the cases here reported I had great doubt as to whether or not the tumor involved the intracranial portion of the nerve As yet there seems to be no indication of intracranial development Certainly it could not have been stimulated to more rapid progress by the operation

In a recent case reported by Vossius (1885), where a myxo sarcoma of the optic nerve was removed, the patient made a good recovery in six weeks, though the neoplasm had apparently not been completely removed from the optic foramen Such cases would seem to indicate that sarcomata of this structure have a less malignant tendency than when involving other tissue

GASTRO-INTESTINAL HÆMORRHAGE IN THE NEWBORN

BY HENRY B HEMENWAY, A M , M D ,
OF KALAMAZOO MICH

I desire to present the records of two cases of a type of disease fortunately by no means common I am led to suspect that the malady may be far more frequent than we know, owing to occasional difficulty of detection by one not on the lookout The first case I report occurred in my own practice and in

my own family As I look back upon it, I see that had I been as watchful as I might have been I would have discovered the evil full 40 hours before the time I first suspected it That lost time was precious I will not say that had the case been recognized from the first the little life would have been spared, but surely its chances would have been better I had never known of such a case A medical friend who was present at the birth of the babe looked through his entire library and only found a slight mention of the disorder, with the comment that the disease was so rare that more space could not be spared for its discussion Another, who performed the post-mortem examination, a physician who has had a large practice for many years, told me that the malady was one heretofore unheard of by him Still another, who graduated in medicine in the "fifties," told me that he did not remember ever to have heard or read of such a case The fifth doctor to know of this little history was one whose hair the suns of more than the allotted three score years and ten have whitened, and he has instructed a grandson in the practice of our art He had a vague memory of having somewhere read or heard of such a case, but had never personally known of one

The fact that the ailment is not often met with is no excuse for passing it over lightly One may meet it any time, and he will have no time to read up The rarity of the affection is therefore a reason why it should be most closely studied

I desire to report these cases for two reasons First, to prevent others from being as ignorant as I was Secondly, to learn from a discussion of the subject by those of a wider experience than mine how such cases may be prevented, and if they occur, how they may be cured

Case I—At 4 A M, Tuesday, March 24, 1887, Mrs H, primipara, æt 26, was delivered at term of an apparently healthy female child, weighing about 4½ pounds The mother is a brunette 5 ft 5½ in high, and weighing ordinarily only 115 lbs Her general health is and has been good, excepting a tendency to that state called "nervousness" She walks erect and with a free, easy gait She has never been in the habit of wearing corsets, and during the time the child was being carried she did not wear her clothes tight Previous to her marriage she was troubled with habitual constipation After marriage she had none of this trouble until she became pregnant During that whole period she was obliged to use various means for keeping her rectum empty Since childhood, in spite of this constipation, she had not been as well as during this period She had no unusual nausea or bad feelings of any kind She could walk with ease and was much of the time in the open air For her constipation she took in the line of drugs salts, aloin, strychnia, belladonna, oleoresin of capsicum, cascara sagrada, podophyllin and senna During the last months she used especially an elixir containing the three last named drugs She is one of four girls—no brothers—all similar in build, and healthy Their father, a Scotchman, always healthy until his last years, when he became rheumatic, died at the age of 51 of erysipelas Their mother, of Yankee and Virginian parentage, is to-day in fair health So far as known there is no hæmorrhagic diathesis in any member of Mrs H 's family, further than that one of the sisters has been troubled with menorrhagia, and for a time she herself was similarly afflicted

Mr H, father of the child, dark-complexioned, æt 30, born in Vermont, height 5 ft 8¾ in, weight 138 lbs Though never robust, yet has had good health for the last dozen years In constitution he resembles his father, also a Vermonter, dark complexioned, never robust, height 5 ft 8 in, weight 142 lbs, lived a literary life and died of pernicious anæmia at the age of 53 In the opinion of the late Dr J S Jewell, consultant, this anæmia was due to capillary hæmorrhages into the duodenum Frequently during the last year of his life, when he came back from stool, he would say, "What passed me was as black as your shoe" The mother of Mr H is still living, in good health, æt 59, she had two other sons, no daughters One child died at the age of 4 months of cholera infantum The other is well, æt 17 Mr H never showed any tendency to hæmorrhagic diathesis By a former wife he had a daughter, always strong

Mrs H began to have pains about 10 P M March 23 Examination showed a vertex presentation, in the L O A positon The first stage ended at 3 15 A M, and the bag of waters broke about 3 45 the next morning In two or three pains more the head was born, and the pain continued until the body was also delivered The cord was of ordinary length It was not tied until pulsation through it had about ceased The baby began to cry before her feet were out, and at the same time she passed a large quantity of what looked to be normal meconium She was tall and slim, and though small, she seemed unusually strong She took well to the breast, was bright and slept well She was neither rocked, walked with, nor jolted, but laid down quietly to sleep During this day and the next she had several passages, all being the same in general appearance

On Friday afternoon she cried some and the nurse thought she had colic I could detect no bloating of the abdomen, but prepared a little peppermint in water, with instructions not to use it unless it was necessary We were unable to explain why the liver should be so active The crying increased At 2 A M Saturday the nurse noticed that the water she washed the child off with was tinged with red I examined the discharges, but could not detect any trace of blood by the artificial light and unaided vision At 5 30 we could see the red coloration in the discharges At 2 o'clock I suspected, and at 5 30 I diagnosticated, capillary hæmorrhage into the small intestines We then remembered that there were two small red stains in what she had spit up I therefore concluded that hæmorrhage had been taking place from the mucous membrane, probably of the duodenum, for an unknown period before birth That it did not occur in the large intestine, nor as the result of injury, was made probable from the fact that the blood was so nearly digested

In the line of treatment I could not get satisfac-

tory information from any work consulted I feared to use strong astringents in the alimentary canal of so young a patient I advised, therefore, the application of warm flannels to the feet, and the administration internally of fluid extract of hamamelis, tr opium and fluid extract of ergot, and the occasional administration of cold water At first I gave the medicines in the water Later I gave the namamelis alone in 20-drop doses every half hour, and water occasionally between times Friday P M and during that night she did not nurse as well as formerly After giving her a few doses of medicine the discharges checked, and Saturday forenoon and about noon she nursed well and seemed stronger After that she did not nurse so well again, the discharges came more frequently, and the strength failed considerably From that evening until she died she was fed entirely by the spoon Sunday morning her breathing was regular and her pulse good She gradually lost strength until about 11 P M, when she seemed to be dying I have never seen such a struggle with death Several times she seemed to be taking her last gasp, and then after a short rest the respiration would again begin For five hours the battle lasted, and at 4 o'clock Monday morning, just four days from the time of birth, the little spirit left its cage

At 9 o'clock, five hours after death, my friend Dr J M Snook performed a post mortem examination We found fair rigor mortis There was nothing peculiar in the external appearance except emaciation I regret to say that the thorax was not opened We found little adipose tissue The colons were firmly contracted, and the entire large intestine empty By inspection we could see no indication of disease except in small intestine We could find no apparent obstruction to the portal circulation The mucous membranes of the stomach, duodenum and jejunum were apparently healthy In the upper portion of the ileum the mucous membrane showed general extravasation of the blood, the membrane being dark and presenting numerous dots where the hæmorrhage had occurred The lower portion of the ileum was healthy, and also the mucous membrane of the colons It is not impossible that the disease had extended farther up and that the medicines had partially corrected the evil We were inclined to think so There was no ulceration or perforation of the bowel

Case 2 —Dr H B Osborne, of Kalamazoo, has kindly given me the history of this case from his own practice A well formed child was born about 6 A M one Sunday The parents were about 25 or 30 years old, both light-complexioned, and in good health Mrs D, the mother, is quite inclined to be habitually constipated, and while carrying the child she occasionally took cathartics and laxatives She is slight in build, but did not compress her body while carrying the child She has since had a child, now several months old, that is well and strong Mr D lost a brother some time ago from consumption brought on, he says, by exposure So far as known this is the only case of hereditary disease in either family, and no member of either family has shown a tendency to hæmorrhagic diathesis Two months before time Mrs D came near being confined as the result of over exercise This child was born after a comparatively short labor, breech presenting After the breech was born the labor was finished quickly by the doctor The cord was short, and at time of birth there was some traction upon the umbilicus All seemed well, however, until Monday afternoon The doctor saw the child at noon and all seemed well I think he was called about 2 o'clock, and at that time the nurse showed him a clot of blood that had just been passed per anum He administered ergot in solution, and perhaps some other remedy, but the child died about 8 o'clock Monday evening, 38 hours after birth

Dr O was inclined to think that in his case the hæmorrhage was caused by traction upon the umbilicus at time of birth In my case I am inclined to think that the trouble was due to the use of drugs to regulate the mother's bowels That it was not due to causes at birth is shown from the fact that the hæmorrhages probably took place before birth These *ante natal* hæmorrhages may explain the light weight of the child It is not impossible, considering the grandfather's death, that there is an hereditary tendency in that direction

In the line of treatment there is little to be said Were I to treat another case I would use hamamelis, perhaps strengthened with a little tannic acid, and ergot I would put confidence in the former in proportion as the trouble seemed to be high up I should aim to give 1 teaspoonful of the hamamelis every hour, and about 1 drop of ergot per hour, according to symptoms I would use milk to sustain the strength I used in my case a little brandy, but I was not pleased with its effect What is needed is *food*, not stimulants Cool drinks should be prescribed, as the effect of cold is refreshing and salutary The extremities must be kept warm by artificial means if necessary The child must be kept quiet If it is much restless or in pain I would give tr opii, gtt j in water, according to symptoms Should the hæmorrhage occur in the stomach, as shown by hæmorrhagic emesis, I might give a few doses of mineral astringents, and were the trouble clearly located in the large intestine I should probably give a moderately strong astringent enema Generally speaking, however, I think mineral astringents are too irritating to use in this disorder The hæmorrhage may be checked only to give place to a more lasting and painful disorder

---

LAVAGE IN THE TREATMENT OF GASTRIC AFFECTIONS

Read before the Philadelphia County Medical Society, November 9, 1887

BY SOLOMON SOLIS COHEN, M D,

OF PHILADELPHIA, PA

Any agent, or any method that promises to enlarge our therapeutic resources against those obstinate conditions of "gastric catarrh," "functional dyspepsia," etc, that are a source of distress to the patient, of annoyance to the physician, and of profit to the

pepsin and patent-medicine manufacturers, deserves at least a respectful consideration The method that I desire briefly to present to the Society this evening—lavage, or irrigation of the stomach—has been employed for many years in Europe, so that it can no longer be considered to be merely on trial In America, however, it has not won general introduction, nor am I aware that any discussion of it has been had before this body This, then, is my excuse for calling attention to a subject in connection with which I have nothing new to communicate

It needed not the discovery of omnipresent bacilli, those evil spirits named "legion" of our modern superstition, floating about, "seeking whom they might devour," to enforce the value of cleanliness The surgeon long ago discovered that clean surfaces would unite more promptly, that a wound kept free from foreign substances and irritating secretions, would undergo a more rapid and more satisfactory course toward repair, than if the conditions were otherwise In the treatment of the more readily accessible mucous surfaces, whether of the eye, the nose, the throat, the vagina, or the urethra, the importance of keeping the parts free from morbid secretions, from the products of desquamation, and other sources of irritation, is not a matter for debate The extension of the same principle to the treatment of affections of the gastric mucous membrane, is but a question of mechanical detail, not of therapeutic justification

Kussmaul, in 1867, employed a doubly-acting stomach pump to irrigate the stomach with alkaline solutions (Carlsbad water), and it is to this observer that we are principally indebted for a study of the method, mechanically and therapeutically It is said, however, by Dujardin Beaumetz, that a French physician, Blatin, had proposed the practice in 1832 It is to another French observer, Fauché, of Paris, who communicated his procedure to the Academy of Medicine in 1879, that we chiefly owe the simplification of the technique by the use of siphonage, a process employed independently by Oser, of Vienna, at about the same time Others have variously modified the details of instrumentation and practice Among those that have contributed most to the popularization of the method, is Dujardin Beaumetz, who applied to it the name *lavage*, by which it is now described

The manner of performing lavage, recommended by the latter observer, is that which I have followed in the few cases in which I could induce private patients to submit to it The results obtained in these cases have been sufficiently encouraging to induce me to continue, at least to propose it, wherever it seems applicable

The apparatus and its employment are sufficiently simple An œsophageal tube with blunt, double-eyed extremity, of flexible rubber, about twenty-eight inches long, and from one-quarter of an inch to a little less than half an inch in diameter—practically an enlarged catheter, and made of similar (the one exhibited having been made by Tiemann & Co , of New York)—is attached by a small section of glass tubing to a soft-rubber tube about one yard in length, into the free extremity, of which a glass or rubber funnel, of from six ounces to eight ounces capacity, is inserted Sometimes the free extremity of the œsophageal tube is slightly stiffened

The patient sits, or stands, facing the physician The œsophageal tube having been dipped into warm water or warm milk, is placed within the entrance of the œsophagus, and is then propelled by successive pushes into the stomach, the process being facilitated by efforts at deglutition on the part of the patient

Many patients quickly learn to introduce and swallow the tube without assistance A mark on the tube shows when a sufficient length has been introduced (say eighteen or nineteen inches) The funnel is then elevated to the level of the patient's forehead, and from a pint to a quart or more of the lavage solution is slowly poured in, the glass junction tube permitting its passage to be watched, and obstruction or attempted regurgitation to be detected The patient's sensations will usually inform us when a sufficient quantity of the solution has entered the stomach As the last portion of liquid disappears from the funnel, the soft-rubber tube is pinched near the extremity, the funnel is rapidly inverted over a receptacle placed upon the floor, and the contents of the stomach are thus removed by siphonage These manœuvers are repeated until the returned fluid is clear

The first introduction of the tube, and possibly the second and third, will occasion more or less dyspnœa, often nausea and retching, rarely vomiting These effects, though partly physical, are largely psychical, and will disappear with tolerance The dyspnœa may be immediately checked by insisting on full inspirations Nausea is overcome as soon as the water enters the stomach, floating the tube away from immediate contact with the mucous membrane In highly neurotic subjects, it may be well to prepare for the operation, at first, by administering full doses of bromides I have tried anointing the end of the tube with a solution of cocaine in glycerin, but cannot claim any striking benefit from the procedure Firm, but skilful handling of the tube is the best sedative

Sometimes during the withdrawal of the solution, solid particles of food (grains of corn in one of my cases) may become impacted in the eyes of the tube, and the flow of liquid will cease A little more of the solution must then be introduced, both to wash away the obstruction and to reestablish the syphon current If the tube should be pushed too far into the cavity of the stomach, it may curve upon itself, and the siphon will not work Withdrawal of the tube for a few inches, will remedy this, if the flow is not readily established, it is said that it may be favored by manipulation of the stomach, and efforts at coughing may be made by the patient I have not had occasion to resort to these devices

When *lavation* alone (washing) is the object of the procedure, a weak alkaline solution is employed, a drachm or two of sodium sulphate, sodium chloride, sodium borate, or sodium bicarbonate, in a quart of warm water, at about 100° F

Should it be considered necessary, however, vari

ous sedative or antiseptic medicaments may be added to the lavage solution Those most highly recommended are resorcin (1 per cent), borac acid (1 per cent), creasote (1 per cent), carbon disulphide water (one part of a solution containing 15 grains to the quart, to two parts of water), charcoal powder (two to four tablespoonfuls), chloroform water (saturated), bismuth subnitrate (two tablespoonfuls to the pint)

In the use of agents like resorcin, carbolic acid, etc , the liability to absorption if the solution be not all removed, must not be forgotten In using what he terms "milk of bismuth," Dujardin Beaumetz advises that the solution be allowed to remain a few minutes in the stomach, so as to allow the bismuth to be deposited, after which the supernatant liquid may be withdrawn

Lavage should be performed when the stomach is empty, therefore, some authors recommend the hour of rising in the morning I have found noon—say four or five hours after a light breakfast—or the same interval after lunch or dinner, to be more convenient for myself, and to answer as well in most instances

One lavation daily is usually enough After a while the intervals may gradually be lengthened, until the process is discontinued

The therapy is sufficiently obvious The effects are said to be most marked in cases of dilatation of the stomach, in which delayed digestion, retention and putrid fermentation of the contents of the stomach, give rise to distressing symptoms In all cases, in which the gastric mucous membrane is in a catarrhal condition, coated with the glairy mucus seen amid vomited matters, or bathed in the sour liquid ejected as "water-brash," in which the production of gastric juice is impeded, or the secretion altered in quality by an abnormal condition of the membrane, extending, perhaps into the tubules, or by the presence of irritative matters, in which fermentation of ingested and retained matters takes place, in short, in the typical case of chronic gastric catarrh or acid dyspepsia, lavage will be found highly useful It removes any undigested matters remaining in the viscus, cleanses it from products of desquamation and morbid secretion, and gently stimulates the glands and absorbents to healthy action In gastralgia, dependent upon the presence of irritating matters, and sometimes in cases apparently idiopathic, lavage with the employment of chloroform or bismuth as a sedative, is said to be productive of cure I have had no opportunity to test the statement personally

In the chronic gastritis of drunkards, the measure is said to be an excellent palliative, nor is hæmatemesis considered a counter indication, unless actual ulceration exists In cancer of the stomach it is useful as a palliative measure, and my first practical acquaintance with this method of treatment was made during my student days, in two cases of gastric carcinoma treated after the method of Kussmaul, with doubly-acting stomach-pump, at the hospital of the Jefferson Medical College, in the clinic of Prof DaCosta

Within the last few years two new applications of the lavage method have been found In 1885, at Kussmaul's clinic, and subsequently by Senator, Rosenthal, and other observers, it has been successfully employed in the treatment of ileus Kussmaul explains this result by the theory of relief to the tension above the point of constriction, caused by gases and accumulated feces, with concomitant restoration of normal peristaltic action Since 1884, Leube and other observers have made chemical and microscopical examinations of the gastric secretions and other matters removed from the stomach at various periods of digestion, and claim to have thus obtained valuable diagnostic indications This subject, however, is beyond the scope of the present communication

While the practice is usually confined to chronic cases, I have had occasion to resort to it in one case of acute indigestion with obstinate vomiting, in a phthisical, slightly hysterical, female, with gratifying result—in that the vomiting, rebellious to diet and medication, yielded to two applications of the stomach tube In this case, before withdrawing the tube, warm milk was introduced into the stomach, a measure advocated by French writers Indeed, there can be little doubt, but that in connection with *gavage*, or forced feeding, irrigation of the stomach assists in maintaining nutrition in phthisis and other wasting diseases

ASEPSIS AND ANTISEPSIS

BY HORATIO R BIGELOW, M D ,
OF WASHINGTON, D C

I have read Dr Ellzey's article "Antiseptics in Medicine and Surgery," in THE JOURNAL, of Oct 8, with more than usual interest, and it is in no spirit of hypercriticism that I object to certain inconsistencies Truth being a correspondence between the order of ideas and the order of phenomena—a just equipoise, so to speak, of the *internal* and *external*, we can only test it by *experience*, and the measure of its worth must be its *verification*

Dr Ellzey has no faith in the surgical antisepsis that obtains largely in most surgical clinics, because the strength of the solutions employed is not germicidal, to be germicidal they would be dangerous to life He uses, nevertheless, sponges, instruments and dressings which he claims are aseptic Has he ever tested his armamentarium with sensitive plates, to see if all the parts thereof were sterile? Has he ever tested his hands and arms just before an operation? Has he ever satisfied himself of the primary sterilization of the catgut? Has he examined the air of the operating room? (See interesting observations made by Dr Fenger, of Chicago) Of what use is it to discard antisepsis in the one case and to practice asepsis in another, unless there be absolute certainty of sterility Dr Fenger says "What influence the asepsis of the material has on the result of the operations as to death or recovery is a question far beyond the scope of these investigations It would require a large statistical material of well ob-

served cases, and more work than could be done by one observer But it may be safe to conclude that it is desirable to work through an abdominal operation with perfect asepsis everywhere, if such a thing is possible The above investigations have shown that such perfect asepsis can be obtained" The asepsis practiced by Dr Fenger are as follows

1 Preparation of operating room, 1 1,000 sublimate used

2 Preparation of operator and assistants, 1-1,000 and 1-2,000 sublimate used

3 Preparation of sponges

4 Testing sponges before used

5 Testing catgut

The sponges and silk were also tested as to their sterility after operations Dr Sternberg recently published an exceedingly valuable paper upon the heat death point of bacteria, showing that the viability was variable

The same holds true of the chemical agents used as germicides, some bacteria being very much more susceptible to the toxic influence than others Of what use is *cleanliness*, if it be not synonymous with antisepsis? Why wash the parts before the operation if it be not with the hope of an aseptic surface? But cleanliness *alone* is not *asepsis*, it is simply a just regard of the great moral canon, which in later days has also grown to be a physiological canon It is done with the primary hope of depriving the parts of that necessary wherewithal for the growth of bacteria It does not kill them, it simply modifies the nutrient Add to this, however, subsequent washings with ether (or lemon juice), and the mercuric chloride, and we not only arrive at an *aseptic* surface, but we have reason to believe that we have killed out any pre-existing colonies We have taken superfluous fat and dirt from the skin (which washing alone with water and soap will not accomplish) which are favorable nutrient media, and we have destroyed any germs, without detriment to the patient's health

We have then an aseptic *surface* and an aseptic *environment* (if all the precautions mentioned by Fenger, and observed by careful surgeons generally, have been attended to), two factors which could not possibly obtain from the use of soap and water alone But although the patient, operator and assistants may have taken sublimate baths just prior to the operation, their exposure to the air, if only for a moment, may make them carriers of germs—and colonies will often appear in the room during an operation, which were absent in the beginning Hence in many operating rooms a strong carbolic spray is kept playing during the entire duration of an operation, *not as a germicide*, but to prevent so far as possible the development of germs from extraneous sources, in a room which had been rendered aseptic Iodoform largely used as a dressing *is* a germicide of suppurative cocci, not only so, but it prevents the wound from furnishing the suppurative changes which are absolutely necessary for the development of the cocci Salicylic and boracic acids used within the abdomen as germicides, have not been followed with bad results, so far as my observation shows me Mercuric chloride I have never seen used within the cavity more than three or four times, and then in small quantity It was followed by no bad results Within the vagina I have seen it used, in all of the accepted strengths, for long periods of time, without bad results I believe that it is *quite* possible to reach all parts of the vaginal tract, by intelligent irrigation, and to rid it of germs by the employment of the mercuric chloride, and although I have seen many hundreds of plastic operations on the utero-vaginal tract in which mercuric irrigation was resorted to, I have never known of one that suffered therefrom

There seems to be really very little real distinction between the two words viewed in the light of general acceptance and practice Dr Ellzey's *asepsis* is merely modified antisepsis An instrument or sponge is rendered aseptic through antiseptic precautions, whether this be accomplished by chemical combination or merely by hot water He uses on instruments and dressings precautions of chemical equivalent which he denies to the body He therefore simply limits his range and practice of antiseptics—for if hot water will prevent sepsis in a certain sense it may be said to be antiseptic Surgical cleanliness and surgical antisepsis are synonymous terms Water or soap and water are not adequate, especially inadequate are they as applied to instruments The germicidal property of the antiseptic is not the only thing aimed at It is used as a preventive of incubation, and as a preventive of such process we aim at *perfect* cleanliness Constant irrigation with a 1 2000 mercuric chloride solution or a 2 per cent carbolic solution upon the vagina are rarely, if ever, attended with bad results Perfect cleanliness, with all that it implies, is best obtained, according to my ideas, and generally obtained by the use of a chemical Boiling water in an *aseptic* room is antiseptic, but there is always an ever present probability that the water may become impregnated from the surrounding atmosphere Kept at the boiling point and immediately used at this temperature is almost impossible, and constant irrigation with it is not practicable Now the entire object of the after dressing is to exclude atmospheric conditions The air then *does* contain a something to be feared, and why use every possible means to avoid a disastrous contingency *after* an operation that is always present while the patient is on the table?

We use *antiseptic* dressings to prevent the formative tissue changes that develop and keep vital germ life, and not solely and simply to exclude air We are never sure that our operating room is aseptic, hence the possibility of latent potency in the air itself—only awaiting the degenerative process to become active We *sterilize* the wound in the best way that intelligence dictates to prevent the changes that are fertilizing elements of bacteria They that rail at antisepsis and cry for cleanliness are really playing upon terms They both arrive at the same end, by almost the same logical process that the surgeon does who uses the sublimate, for surgical cleanliness implies surgical antisepsis

The only question is, How best may we obtain surgical cleanliness? Are these microorganisms the specific source? What relation do the "ptomaines"

bear to the poisonous processes? To what extent may mental conditions engender the pathological processes we now attribute to "ptomaines?" Bacteriology, though still in swaddling clothes, is fast learning to walk alone To the surgeon the infant has been as great a surprise as was the Great Physician to the Hebrew doctors It has given them a knowledge of the destruction of these organisms outside the body Dr Ellzey says we do not know the optimum of temperature for septic germs Dr Steinberg's tables are fashioned to meet just such doubts To his objections of the strength for germicidal properties of the mercuric chloride, it may be said that we have a more than approximate knowledge not only of the strength of the chloride necessary to act as germicidal in the different kinds of microorganisms, but that this investigation has embraced many of the other chemical agents employed for similar purposes There can be no single test of germicidal strength Spores are often wonderfully resistant, and the spores of anthrax require much stronger solutions than do spores of other germs The spores of anthrax are the only ones that resist the action of creoline But pus germs and the usual run of bacteria with which the surgeon has to do battle, are more easily affected

Dr Ellzey writes, "It is for the destruction of bacteria and their spores that we use antiseptics" This is but a partial statement of the case, since in their use we also hope to change the media, or rather to preserve the media at normal, so that the pathogenic bacteria may not develop Dr Ellzey further says, "The use of carbolic acid should be confined to the disinfection of instruments, and for this purpose its strength should be rather more than 1 to 10" The statement seems to me to be unsound, In the first place it may be doubted if this strength would make a contaminated instrument thoroughly aseptic The most reliable agent is dry heat, and the most convenient apparatus a Koch's sterilizing oven There are spores that resist a 10 per cent carbolic solution, and hence for germicidal purposes we use the bichloride That a few, a very few deaths in comparison with the thousands treated, may have been directly due to mercuric poisoning may not be gainsaid, but we do not discard ether, chloroform or opium because deaths have resulted from their use Individual susceptibility and idiosyncrasy is not always discoverable beforehand I have seen the mercuric solutions in strength from 1-1000 to 1 5000 in many hundreds of plastic operations, with irrigation lasting from fifteen to forty-five minutes, without any bad results I have seen tests made upon the vaginal secretions just after such irrigations in which no pathogenic germs were discoverable I have seen certainly four or five hundred women whose uteri were curetted and in whom uterine mercuric irrigation was before and after the operation and there were no symptoms of intoxication I have seen its employment in Spaeth's and Braun's wards in Vienna for three months, and heard of nothing untoward though the material was vast Ehrendorfer frequently introduces pencils containing 70 grains of iodoform into a uterus, after labor, without any symptoms of iodoform intoxication Martin's operating room is always thick with carbolic spray, but he never has had unpleasant results although some of the spectators present found it irritating

But after all, the discussion is hardly necessary for Dr Ellzey's asepsis is very good, though limited antisepsis He renders his hands, arms, sponges and silk aseptic by antiseptic means, and washes the part to be operated upon with mercuric chloride It would be well for surgery in general if all surgeons would be equally conscientious

Berlin, Oct 27, 1887

RAPID DILATATION OF THE CERVIX UTERI, ITS AGENCY IN THE TREATMENT OF FLEXIONS, STRICTURE, CHRONIC ENDO-TRACHELITIS, CONICAL CERVIX, DYSMENORRHŒA

Read before the St Louis Medical Society, Nov 26, 1887

BY YOUNG H BOND, M D,

GYNECOLOGIST TO ST LUKE'S HOSPITAL, CONSULTING PHYSICIAN TO ST LOUIS FEMALE HOSPITAL ST LOUIS

To Dr Mackintosh, of Edinburgh, is due the credit of having first directed the attention of the profession to the mechanical cause of certain cases of dysmenorrhœa, and the suggestion of mechanical means for its relief, consisting of gradual dilatation of the cervical canal by means of flexible bougies, or by metallic rods of gradually increasing volume

Rigby was the first to use a dilator with steel blades, which were opened and left for some time in the cervix Raynaud, of Montauban, Simpson, Sims, and others sought to accomplish the same ends by the use of different materials, as dilators, such as metallic stems, wax bougies, aluminum and other metals Simpson and Sims lived to repudiate this method of treatment, and substituted therefor incisions In 1871, Dr J Protheroe Smith, of London, in setting forth his plan of treating certain cases of dysmenorrhœa and sterility, said that after giving Dr Simpson's plan of incision a fair trial, he gave up the use of the hysterotome, and adopted forcible dilatation, using a dilator made after the model of Heurteloupe's lithotrite, by which he conceived it practicable to dilate permanently the constricted os internum, and afterward, when necessary, to give the normal shape to the os tincæ, by dividing it laterally at the commissure of the labia uteri

He confined this treatment to simple stricture of the os internum, and narrowing of the cervical canal and os, excluding as inapplicable all cases, even of this class, until all inflammation of the parts had been relieved His method consisted in accustoming the uterine canal to the presence of a metal bougie, introduced daily, of increasing size to a number 10, then the dilator was employed cautiously every second day, desisting from dilatations so soon as pain was produced

Proceeding in this way, in the course of a few days or weeks, as the case might be, he succeeded in dilating the canal to the extent of an inch or an inch and a half After this the dilator was used daily

for two or three days, and afterwards at increasing intervals, to maintain the patency of the parts until they permanently healed in the state of distension

In 1873, Dr John Ball, of Brooklyn, read a paper before the King's County Medical Society, of N Y, advocating dilatation of the cervix uteri in a far more rapid, forcible and heroic manner than had even before been supposed prudent or admissible, and recommending it as a means of relieving stricture, endo cervicitis, flexions, etc Accompanying this paper was the report of a number of cases of mechanical dysmenorrhœa dependent upon the above conditions that had been completely cured by this daring mode of treatment Dr Ball accomplished at one sitting, or treatment what Dr Smith achieved by gradual steps, the one gave to the operation an extensive field of application, the other a limited one

The method as practiced by Dr Ball, with variations of devices and technique, and its indications, as presented in his paper, has received the sanction of all that have practiced it sufficiently to judge of its merits

Its utility and worth are fully recognized by the daily practice of such men as Goodell, Wiley, Marcy, Ellinger, Schultze, and others Almost without exception, they that have had extensive experience in this method of treating mechanical dysmenorrhœa, and the inflammatory states of the uterus originating therefrom, speak in the most encouraging manner of its efficacy and safety, while its chief opponents are to be found opposing it upon theoretical grounds, and not because of any adverse experience in its practice

The practical ends of most cases in which forcible dilatation is indicated, can be met by one of two degrees of dilatation, viz dilatation to a moderate extent, sufficient to permanently increase the cervical canal, of relatively moderate insufficiency, to admit the use of the curette, of the ready and efficient application of remedies to the endometrium and cervical mucous surface, to facilitate explorations of the uterine cavity, etc, this method of dilatation I daily practice at my office

The second degree is that of divulsion, the practice of which always presupposes the use of ether or chloroform, its chief indication is to be found in the cure of flexions, and conditions incident thereto, the ready and thorough exploration of the uterine cavity, for diagnostic purposes, to facilitate the removal therefrom of tumors, growths, etc, for the relief of conical and elongated cervix, stricture and consequent sterility

Before detailing the minutiæ of my method of procedure in using rapid dilatation it may be well to remind you in a general way of the modes of treatment in general use for the relief of those forms of mechanical dysmenorrhœa involving a diminution or interruption to greater or less extent of the uterine or cervical canal

The generally recognized treatment, for a number of years since, has consisted in either dilatation or incision The methods of dilatation, gradual and rapid, the means of the former, sounds, specula, tents, sponge, sea tangle and tupelo, the means of the latter, expanding instruments, Ellinger's, Wiley's, Goodell's, Sims', Schultze's, Wathen's and others, incisions are practiced after the method of Simpson, by means of the hysterotome, or by Sims' method, or by the combined method The unsatisfactory results from the use of sounds, the failure to effect continued perviousness of the canal, has caused them to be well nigh discarded in this connection

Tents are still used to a considerable extent, notwithstanding the fact that they are sadly disappointing in results sought for, a common feature of failure with them all is a want of permancy of the dilatation accomplished Their action is slow, tedious, and uncertain, involving much loss of time with very little, if any, compensating advantage The sponge tent as a dilating agent, is the most efficient of its class, and at the same time the most dangerous, because of the liability to septicæmia from its use, a result that has followed in an uncomfortably large number of cases

Notwithstanding the indulgence of much ingenuity in their antiseptic construction and use incisions are wrong in principle, in some instances necessarily uncertain in extent of tissue divided, more or less dangerous, and unless immediately followed by the plug or stem pessary, or by the daily use of the bougie or dressing-forceps, utterly fail of their purpose

From practical observation and experience, I have become fully committed to the propriety, wisdom and efficiency of rapid dilatation for the relief of all forms of what might appropriately be termed obstructive dysmenorrhœa, conditions embraced in stricture, conical cervix, flexions, etc There are those that advance extravagant claims for electricity in the treatment of the conditions that I have enumerated I regard it as an important subsidiary agent, but as a principal agent of treatment I do not believe that it is comparable to divulsion in the correction of strongly established flexions I regard it as a most important means in the effectual treatment of endometritis, and of permanent value in the relief of that hitherto most obstinate and persistent disease, endo cervicitis I believe it to be the only means of radically curing firmly established flexions, certainly it is the only means that end in my hands

In practicing forcible dilatation to a moderate extent no anæsthetic is needed, perfect antiseptic precautions should be observed, exercise immediately thereafter, beyond a moderate extent, should be prohibited The method that I pursue in practicing dilatation in the second degree, that of divulsion, is the following

Having previously by careful examination excluded the possibility of any extra-uterine inflammation or condition, neoplasm, etc, that might contra indicate the measure, regard being given to the proper evacuation of the bowels and bladder, and all needed instruments immersed and kept in a 5 per cent solution of carbolic acid pending the operation, pledgets of absorbent cotton pressed out of a bichloride solution, 1 2000, just ready, the patient being thoroughly etherized is placed in the Sims' position, the vulva and surrounding parts are sponged off with a 1 2000 bichloride solution

A Sims' speculum being introduced, the vagina, cervical and uterine canals are thoroughly cleansed with the bichloride solution, the anterior lip of the cervix is seized with a double hooked tenaculum and drawn down toward the vulva, then taking in hand a Wiley Sims' dilator, I dip its blades in pure carbolic acid, and having shaken off any excess of acid, I introduce them into the cervical canal, and dilate sufficiently to readily admit of the introduction of the Sims' dilator, which I prefer at this stage for the reason that the dilatation can by its use be regulated more easily as to duration, and its extent more easily determined The advantage of the Wiley Sims' dilator consists in its more ready introduction into a distorted canal in consequence of its small points and curved direction

I usually consume from ten minutes to a half hour in accomplishing the divulsion, the degree of resistance determining largely the length of time The dilator removed, should there exist endo cervicitis, as is usually the case, with a Sims' instrument, I thoroughly curette the mucous lining of the cervix, then with the bichloride solution I again cleanse the genital tract, and taking from a solution of pure carbolic acid one of Wiley's hard rubber plugs, of suitable length and size, I pass it into the dilated passage, and secure its retention by means of antiseptic tampons

Should no untoward symptom arise, this plug is left in for forty eight hours, at the expiration of which time it is removed and the entire genital passage antiseptically cleansed and another similar plug introduced, the same antiseptic precautions being observed as previously, and this course is continued for one week The plug is then left out for several days, after which it is re introduced with the same precaution as before and worn for twenty-four hours, and so on till the approach of the second menstruation following the operation

The use of the plug is intermitted during the menstrual flow, reference to which should determine the time of the operation The patient during all the time that the plug is worn is confined to her bed, and most invariably assumes the dorsal position, it being the most comfortable Her diet is light and simple during the first week For the first two or three days after the operation the bowels are confined and the water drawn off, an opiate enema is administered should the occurence of pain require it, though the amount of pain complained of is usually inconsiderable

Rationale It is not difficult to understand the rationale of this procedure in the treatment of stricture of the cervix, whether it be congenital or acquired, for by it we tear asunder the circular muscular fibres of the cervix, we rupture them at various points, influenced by their varied attachments and relations, one set of muscles here, another there, and so on throughout their distribution, rather than at some fixed and definite line, as in the case of the incision If the circular fibres of the cervix all acted from the same fixed point, there could not exist the objection to the practice of incision, that I entertain, and I believe very justly

By incision injury is done to the longitudinal as well as the circular muscular fibres, by dilatation the integrity of the circular fibres is interrupted at various irregular points, whilst that of the longitudinal fibres being unaffected is exerted in shortening the cervix and increasing its transverse diameter And practically, this is just what I have observed after divulging a conical, narrow and elongated cervix It is not necessary to amputate any portion of such a cervix, as has been improperly taught—divulsion gives it normal shape and function

The immediate agency of dilatation in the treatment of endo cervicitis has already been sufficiently indicated, its mediate effect lies in removing the stricture or flexion, of which endo cervicitis is the result

In treating of the *modus operandi* of divulsion in curing flexions, I do not think it necessary or essential that I should enter into any extended consideration of the subject of flexions, suffice to say that I regard flexions or distortions as consequences of malnutrition of the uterus, occasioned by some infirmity or depravity of the general system, either uterine or extra uterine, involving an embarrassment of the nervous or vascular supply of the uterus, or possibly implicating both the nervous and vascular elements

As specially pointed out by Graily Hewitt, malnutrition of the uterus is manifested by undue softness of its walls, the impairment of the condition of the tissues results in a loss of that normal healthy rigidity of the walls of the uterus by virtue of which it preserves its shape and form amid the buffetings of surrounding organs If, during the period of uterine ramollescence, the isthmus be fixed by utero sacral cellulitis, a moderate excess of intra abdominal pressure will occasion anti-flexion, or if there be fixation of the cervix by the bladder systole, with a position of the uterus favoring retroversion, excessive intra-abdominal pressure will produce retroflexion Fixation of the cervix, as indicated by D Berry Hart, is almost an essential in the dynamics of flexions

The uterus having once lost its physiological form, flexion having occurred, is unable by any inherent capacity to effect its own restitution, and when in the course of events there comes a repair of the vascular and trophic lesions, that lead to the undue softness and pliability of its walls, and in consequence there is substituted their physiological firmness, condensation and tonicity throughout, except in certain parts immediately engaged in the flexion, then there will be appreciated the anomalous fact that the conditions of health entail the perpetuation of a consequence of disease

The indications then for the cure of an established flexion will be found to consist in the reestablishment of the physiological state of the uterine walls throughout, and this can be accomplished more readily, certainly and effectually by the treatment that I have indicated, than by any other means that I know of By means of it we break up all adhesions, we straighten the canal, we change the muscular tissues at the point of flexion from an abnormal to a normal state, and we establish the circulation

upon a new and uninterrupted basis By it we span that breach of nutrition that leads to the flexion, with its chain of pathological consequences, and we release our patient from her protean ills

NOTES ON HOSPITAL CASES.

VESICAL CALCULUS, MEDIAN LITHOTOMY — RECOVERY RHINOPLASTY, INDIAN METHOD

Read before the Medical Society of the District of Columbia, June 1, 1887

BY JOHN B HAMILTON, M D,

SUPERVISING SURGEON GENERAL OF THE U S MARINE HOSPITAL SERVICE PROFESSOR OF SURGERY, GEORGETOWN UNIVERSITY

I regret extremely that my time has been too much occupied to comply with the request of the Corresponding Secretary for a systematic paper, but it occurred to me that the notes of some rather unusual hospital cases might prove interesting to the members of the Society They are therefore presented without alteration from the case notes

Vesical Calculus, Median Lithotomy—Recovery—Case 1 —M L Underwood, sailor, æt 22, admitted to Marine Ward, Providence Hospital, Washington, suffering from an impacted calculus of the urethra, June 10, 1886 He was placed on the operating-table and I found the calculus in the urethra anterior to the bulb An attempt was made to seize the stone by means of the alligator forceps, but it slipped back into the bladder No further operation was attempted at that time, and in a day or two he passed the stone during micturition He was discharged June 25, 1886 He was again admitted January 13, 1887, suffering from the usual symptoms of stone in the bladder, pain more or less constant in the penis, and occasionally a pinkish tinge to the urine There was no hæmorrhage His general condition was excellent, but the vesical pain was severe On passing a sound the stone was discovered, but not very distinct click, and sometimes could not be felt

Median lithotomy was performed by myself in the presence of the class, Jan 30, 1887, and the stone found encysted in the anterior wall of the bladder There was much difficulty in its removal, which was only effected by directing a strong water current against the wall of the bladder He recovered without difficulty, and the patient was discharged February 25, 1887 The stone is one of the common uric acid calculi

Case 2 —Henry Heil, native of Germany, æt 18, admitted to Providence Hospital May 3, 1887 He was of strumous diathesis and his urine contained 10 per cent of albumen On sounding I discovered a stone just behind the prostate He was suffering greatly and was in bad condition Median lithotomy was performed by myself May 8, and an adherent stone found It was dislodged with the scoop, and extracted in the usual manner The bladder was washed out through the wound for two mornings with a weak solution of bichloride of mercury Part of the urine passed by the natural channels on the fourth day, and on the fifth day the wound was closed The patient was discharged recovered May 23, fifteen days after the operation The specimen is a very beautiful one, of the oxalate of lime variety

Rhinoplasty — Indian Method. — John Sheehan, Irishman, æt 35, lost his nose in Ireland in 1861 He had small pox and subsequently syphilis, but the ulcer of the nose following the small pox was slow in healing, and the nasal cartilage was entirely destroyed There were two minute openings to represent the nostrils, but the face had flattened, and only the bridge of the nose was left The patient was admitted to Providence Hospital, and rhinoplasty performed by me January 3, 1886 The operation was done by the Indian method, the flap being raised from the frontal bone, including the periosteum The new nose united by first intention, and a little more than a year after the operation I had his photograph taken, which shows his present appearance, after ample time has elapsed for the usual shrinkage

While this man cannot be said to be in any degree handsome, yet the operation greatly improved him He was frightfully disfigured by the small pox, and the deformity of the lip is due to that cause, and however much one may cavil at his personal appearance, it must be conceded that a happier man never left the hospital As will be seen by the photograph, the wound in the forehead healed without leaving a very prominent scar

NOTE —Dr Martiny, of Lyons, France, has recently brought to the attention of the profession a new form of artificial nose (porcelain), by which the spectacle frame is dispensed with, a maxillary plate is required, which holds the nose in place by means of an upright rod (*Trans Ninth International Medical Congress*, 1887)

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS —VOLKMANN concludes his paper on surgical tuberculosis (See preceding numbers of THE JOURNAL) with some *general considerations* on the subject

36 The tuberculous character of an affection is not to be doubted when inoculation gives positive results, when the tubercle bacillus is demonstrated, and when the anatomical examination shows the well-known structural changes in the diseased tissues All three conditions are present in the affections described above On the other side, however, it is as yet not proved that tuberculous tissue must *always* present the follicular contraction

37 The spread of tuberculosis takes place through different channels and in very different ways

a The original focus grows

b By the invasion of the tuberculous virus (bacilli) into the lymphatic vessels from the original focus This probably extremely frequent, or almost regular occurrence does not, as a rule, lead to generalization, because the lymph glands not only retain specific pathogenic germs, but in many cases they evidently destroy them The significance of the lymph glands as protective apparatus and filters in local infectious processes is not yet sufficiently appreciated Generalization is, therefore, still very far off, even when the lymph gland becomes tuberculously infected and gravely diseased, as the virus, in case it should leave it and go further, will be retained in glands situated higher up Generalization takes place only when the last lymph gland between the diseased part and the blood current is infected, or the thoracic duct itself becomes diseased

c By the penetration of the tuberculous poison into the serous sac from a neighboring tuberculous focus, and that happens either by the extension of this focus to the internal wall of the sac, or by the invasion by products of suppuration and softening, that contain bacilli The farther spread then takes place in part by the fluid (synovial, exudation, etc) in the sac, and partly by the displacement of the sac-walls by the functional movements of adjacent structures The danger here is especially on account of the size and importance of the serous sac, its lymphatic connections, and further, on whether the sac be soon surrounded by a layer of granulations, that acts as an impossible barrier (though perhaps this has already been done before the introduction of the poison)

d By the tuberculous poison being carried in in the same way, or by the products of suppuration and breaking down in canals and cavities lined with mucous membrane, in which the poison either stagnates, or has to pass out of the organism by roundabout paths in which the mucous membrane is infected by contact, and new miliary eruption takes place The most unfavorable case is, of course, the lungs canalized by the bronchi, in which the virus sets up new foci not only in the bronchi and their immediate surroundings, but the larynx also becomes infected, and, as the sputum is swallowed, the intestines are also infected

e By the penetration of virus from a neighboring focus into a non thrombotic, usually enlarged vessel, especially a vein, or into a lymph tract leading directly into the circulation, so that generalization, acute general miliary tuberculosis, follows Tuberculous disease of a vein-wall from an adjoining focus is to be regarded as the most common cause of this general miliary tuberculosis

When we consider these possibilities we are immediately struck with the fact that tuberculous affections of the bones, the skin, the cellular tissue, the joints, and of the lymph glands are much less dangerous than those of the respiratory organs or of the intestinal tract Fistula ani is, thus, unfavorably situated, since the infectious material can be best quickly carried outwards So far as the danger is concerned, tuberculosis of the urinary organs is no more favorably situated than that of the lungs and intestines Tuberculosis of the testicles can be successfully treated by operation so long as the cord is not diseased

38 The *susceptibility to the tuberculous virus* is in man restricted to certain individuals, and in these to certain times, and to certain organs and tissues

39 This susceptibility is generally received, in the forms of disease with which the surgeon has to do, by hereditary infection But the clinical material of hospitals and clinics is less valuable for statistical purposes here, because the patients can usually give but little information in regard to their immediate relatives or in regard to more remote blood relations The experienced old family physician will, I believe, always declare that fungous inflammations of joints, caries, tuberculous tumors of lymph glands, and the like, do not occur, as a rule, in healthy families — *Langenbeck's Archiv*, Bd 33, Hft 1

(To be continued)

SCRAPING IN SUBCUTANEOUS ULCERATION —IN an article on "Scraping in Surgery," MR T PRIDGIN TEALE, of Leeds, says It is only in recent years that surgeons have recognized how great a power they have acquired over indolent unhealing surfaces by the introduction of the scraper We are mainly indebted to Volkmann, who, in the "spoon" called by his name, has put into our hands an instrument by which indolent granulations, the lining of sinuses and abscesses, unhealthy ulcerating surfaces, lupoid ulcers, and even malignant growths, can be roughly rasped away, leaving a sound surface well supplied with blood vessels, and disposed to fall into rapid healing To the out-patient departments of hospitals this new power should be an inestimable boon Cases of strumous sores and sinuses, and ulcerated legs, that reappeared week after week, and month after month, can now, by the expenditure of two or three months in hospital, be turned out healed, or so far advanced in healing that a week or two of home care will complete the cure Even ophthalmic surgeons are falling under the spell of this new power, and are learning to compress, within a few days, the treatment of cases that often ... ed on a

weary course of attendance for months Such are tinea tarsi, ulcers of the cornea and granular lids, eczematous ulceration of nostrils, lips and eyelids

Subcutaneous Ulceration —My earliest experiences in scraping were in those remarkable cases of extensive subcutaneous ulceration that show almost an incapacity to heal, and that, from their superficial likeness to the sores and sinuses leading to dead bone, I used to speak of as "necrosis of fascia," acknowledging, at the same time, that the name was indefensible In such cases we find large sores with sinuses leading to extensive cavities between the cutaneous tissues and the fascia covering the muscles, lined with granulations and more or less of half sloughy areolar tissue These undermining are often very extensive, and involve, at times, half or two-thirds of the subcutaneous area of the thigh or leg, the lower extremity having been, in my experience, the most frequent seat of this kind of trouble Formerly we should have said that such a surface could not heal because the patient was strumous or of weak constitution Now we can almost guarantee that all, however extensive, or of however long standing, shall be healed in a very few weeks

The worst case of the kind that ever came under my charge was that of a girl about 18, whose left leg and thigh were covered with sores, from which sinuses led to undermined patches of skin, so extensive that in consequence the leg was rigidly fixed at an acute angle with the thigh, and she appeared to be a hopeless cripple—aged and worn out in appearance, and such as one might have condemned as hopelessly strumous The course of treatment in such a case, spread over two or three operations, would be as follows All visible granulations are roughly scraped off a series of sores The cavities and sinuses are then in like manner stripped by scraping off their granular, ulcerative, or sloughy lining, and these undermining cavities are provided with effective drainage by incisions, at the extremity of every pouch or pocket, perhaps an inch and a half in length, and T-shaped or semicircular, as a security against premature healing By these incisions it is provided that no subsequent effusion of blood or serum can possibly collect and lodge All fluid must ooze out and escape, and the walls must fall into contact, and in the main adhere by first intention The cavities are then well syringed by carbolic acid solution (1 in 60), and generally are lined by a thinly spread coating of iodoform The whole is packed up with an abundant padding of salicylic silk or absorbent cotton-wool charged with with an antiseptic drug Occasionally it is well to insert a drainage-tube from point to point As there is at first considerable sero-sanguineous oozing, it is wise to change the dressing in about twenty four hours, dressing the new surfaces freely with iodoform, and covering again with a large absorbent pad, which ought not to need renewal for several days In a fortnight all but the drainage points are, as a rule, healed The girl in question was, in a few weeks, healed of her sores, was thriving in appearance, and actually recovered full use and movement of her leg without any aid whatever from passive motion or division of tendon —*Liverpool Medico-Chirurgical Journal*, January, 1887

PYRIDIN IN ASTHMA —In the course of former experiments RENZI observed that besides lessening the number of respirations, pyridin also increased the energy of the heart's systole He therefore tested it in severe cases of heart disease, two of aortic insufficiency, one case of pericarditis, one of parenchymatous nephritis with weakened heart, and one case of mitral stenosis

He first gave the pyridin in doses of from 6 to 10 drops, diluted with two or three drachms of water, and gradually increased the dose to 25 drops In the cases of nephritis and mitral stenosis there was no improvement, but in the others there was a strengthening of the systolic impulse, and the number of beats was lessened The blood-pressure was increased A systolic action was allayed more readily by pyridin than by digitalis, and it has no cumulative effects Angina pectoris, that often complicates such cases, was more benefited by pyridin than by anything else —*Centralbl fur klinische Medicin*, No 46, 1887

TREATMENT OF TAPEWORM —DR K BETTELHEIM recommends the following mixture, made into pills

Ext filicis maris aeth	10 grams
Ext pumicæ granati	10 "
Pulv jalap	3 "

℞ Make 70 pills, coat with keratin

From 15 to 20 of these are to be given on the day of fasting, which is preceded by purgation, and the remainder of the pills are given on the following day, in two or three hours When necessary, this treatment is followed by a purge The object of the keratin coating is to prevent the solution of the pills until they pass into the intestines In this way nausea, vomiting, and other discomforts and annoyances so often associated with the taking of vermifuges, are avoided —*Centralbl fur klin Med*, No 46, 1887

COCA EXTRACT IN PAINFUL AFFECTIONS OF THE STOMACH —In the last two years and a half D'ARDENNE has treated many cases of painful affections of the stomach with coca extract, for the purpose of relieving the pain In the cases associated with structural lesions of the stomach-walls the relief was of short duration and incomplete, but in the purely functional cases the pain was always caused to disappear, however severe the attack, and though the usual remedies had been employed in vain The dose used was 2 grains of the extract, every two hours —*Revue Gen de Clinique et de Therapeutique*, Oct 6, 1887

CHLORAL HYDRATE IN RABIES —BROWN SEQUARD reports a series of experiments on rabbits and birds, in which he produced a kind of rabies by injecting oil of tansey This rabies he was able to control by the vapor and subcutaneous injections of chloral Brown Séquard thinks that, from analogy, chloral is a preventive of true rabies He refers to his previous writings on this subject, and to cases in man in which he exemplified his theory —*L'Union Medicale*, Nov 5, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

THE HYGIENIC TREATMENT OF STRUMA

DR WILLIAM ALEXANDER, of Liverpool, records, in the *Liverpool Medico-Chirurgical Journal*, his experience in the treatment of struma at the Liverpool Workhouse Infirmary At this hospital the so called strumous ophthalmia, and strumous disease of the joints and glands constitute the staple diseases of the children patients

For the treatment of strumous ophthalmia a country house was selected near the city, and a careful, competent and zealous nurse appointed, and to this place the children were sent as soon as the acute symptoms of ophthalmia had passed away Here the local treatment of the eyes was continued, being aided by the fresh air, plenty of exercise, and more wholesome surroundings The treatment seems to have been successful, though the author's language is somewhat obscure "Since that time only a few cases of ophthalmia percolate the Workhouse Infirmary, to be finally cured at Maghull (the place of the country house) " But he further says that no eyes are now lost, and that not many children exhibit those patchy eyes that were at one time an almost certain result of residence in workhouses Dr Alexander concludes that "a thorough cure of strumous ophthalmia by country air is the only remedy worth considering in chronic cases The part of the country to which the child should be sent is not a matter of any great importance, provided the place is healthy and not too cold "

In regard to surgical treatment of strumous glands of the neck, Dr Alexander looks upon this with more favor as his experience grows, especially taken in connection with the medicinal and hygienic treatment "The most favorable case for operation is when a single gland inflames and is about to suppurate By a small clean incision the capsule of the gland is exposed, the capsule cleared, and the whole gland removed entire The incision is accurately closed, the hole whence the gland was taken is drained, and a scarcely perceptible scar takes the place of a sinus that would under expectant treatment have kept open for months, leaving a puckered cicatrix at the end of that time Any enlarged movable glands are also removed at the time of operation " When the capsule of the gland is so thinned or adherent to surrounding structures that it cannot be removed entire without a formidable operation, it is opened by the usual small incision, the pus evacuated, and the capsule carefully dissected out The cavity is then dusted with iodoform, provision made for drainage, and the wound carefully closed To attack the very bad cases of scrofulous glands of the neck, the surgeon must, of course, be very certain of his anatomical knowledge of the neck, so as to avoid important structures in opening the sinuses that generally lead down to cavities filled with strumous débris Dr Alexander uses the finger as a director and a narrow gouge as an excavator, the cavity is cleared out and explored, especially as to any communications existing between it and other sinuses If such communications exist the sinuous tracts are well cleared out, opened up, and filled with carbolized oiled lint, iodoform gauze, or some other antiseptic material If irritation and inflammation are produced by this procedure a warm linseed poultice gives great relief, which should be removed when the inflammatory symptoms have subsided, usually in twenty-four or forty-eight hours, and the disinfecting treatment be resumed until the cavity heals from the bottom Recurring glandular enlargements and abscesses, near to or remote from the seat of operation, should be attacked in the same way, cleaned out and freely drained, all the sinuses and deposits of cheesy material must be completely eradicated

Simple glandular swellings, indolent and firm, should never, in the opinion of Dr Alexander, be attacked by the knife However formidable they look, he says, they disappear very rapidly under the medicinal and hygienic treatment he describes Internally he uses the syrup of the iodide of iron, and externally the linimentum potassii iodidi cum sapone. "Blistering by iodine paint, or the application of the tincture externally, seems to be harmful rather than beneficial Many of these glandular swellings *arise* from the irritation of the throat or scalp or teeth,"

and in the treatment of them he would avoid all irritation The neck should be kept comfortably warm by some soft clothing, or by cotton-wool The liniment is rubbed in very gently, but effectually, before a fire, and the cotton-wool applied as soon as the inunction is done A thin and anæmic patient of course needs cod-liver oil and good food, but if the patient be plump and fat, as is sometimes the case, the oil is not necessary, and the food should not be too oleaginous Very stimulating diet should be avoided in all cases "But the diet is a secondary consideration, and depends upon the extent to which the hygienic treatment can be carried out "

However well it may be built and appointed, a hospital is not the place for the hygienic treatment of struma "A sedentary, lazy, well-fed life is the least productive of an active and efficient circulation of either blood or lymph Patients with glandular swellings not requiring surgical treatment should move about as much as possible in the open air, and receive medicinal treatment at home rather than in a hospital The hygienic treatment, to be of marked benefit, should last over two months, and more While over-fatigue is to be avoided, the patient should take as much exercise in the open air as possible, the throat being well protected from wind and rain While a low-lying country is not so well suited for these cases as a hilly one, and while the sea-coast is preferable to the inland, yet it must be said that the country, whatever it may be, is better than the city, and infinitely better than the wards of a hospital

In the hygienic treatment of strumous joint disease time, next to situation, is the chief element of success Surgeons that have read Dr Alexander's Jacksonian prize essay on hip disease will read with interest what he has to say of the hygienic treatment of strumous joints He finds that a sanitarium that is suitable for strumous glands does not agree so well with cases of strumous joint disease, and he is inclined to look upon the difference rather as indirect and accidental than as attributable to purely climatic influences Of course, locomotion being impaired in cases of strumous joints, a hilly or mountainous country is less suitable for them than is a flat country When the joint disease is so far cured as not to seriously interfere with locomotion, the patient will do well almost anywhere in the country When the patient is sent to the country from a hospital after a long and acute illness the change is, of course, very great, and is aptly compared to the cold morning plunge of a healthy person He should be well protected, and at first the stay out in the open air should be limited Such a patient should not be subjected to hospital discipline for form's sake

TYPHOID FEVER AND DEFICIENT WATER SUPPLY

During the last few years, many instances have been chronicled in both the medical and secular press, suggesting an important connection between the unusual prevalence of typhoid fever and very low water in the streams, wells or other sources of water supply During the latter part of the past summer and autumn, in many parts of the Mississippi Valley, an extraordinary drouth has prevailed, not only drying up the smaller streams and wells, but reducing the water in the larger rivers to an extraordinarily low level, and coincidently come reports from many localities of the unusual prevalence of fevers, especially of a typhoid type, and in some of dysentery also During the last few weeks, in Cincinnati, where the Ohio River has been lower than at any time for six or seven years past, the typhoid fever has become so decidedly epidemic as to attract the attention of all classes, and especially of the medical societies of that city The disease is reported as not unusually severe, but the number of cases is so large as to cause the number of deaths reported to have reached forty per week

While we do not doubt the importance of the coincidence of extreme low water and typhoid fever, etiologically, some facts have passed under our observation that suggest the importance of two other factors of importance beside the low water One of these is the occurrence of a season of unusual high water, or flood, immediately preceding the season of extreme drouth, and the other is a marked deficiency in atmospheric currents or winds during the dry part of the season, as compared with the average of a series of years in the same localities Our attention was attracted to these additional factors or circumstances during the summer and autumn of 1881, when there was an epidemic prevalence of typhoid fever in Chicago and its suburbs During the eight months from April to December of 1881, there were reported to the Health Office 527 deaths from the fever, when the usual number for the same months for the two or three preceding years was less than 200 each year In searching for the causes for so great a prevalence for that year, it was ascertained that an unusual flood had existed in the months of March and April, after which there had not been sufficient rainfall to fairly wet the dust of the streets until the end of the summer months, and the records of the Signal Service station showed an aggregate of several thousand miles less of atmospheric currents than in the corresponding part of the preceding years

DEATH OF SIR WILLIAM MCARTHUR —Sir William Mc Arthur, Mayor of London in 1881, and who will be remembered by the visitors to the Seventh International Congress that attended the reception at the Mansion House, died suddenly on November 16, after hurrying to catch a train

SPECIAL ARTICLE.

THE CONGRESS AT WASHINGTON

For the purpose of giving our readers impartial opinions concerning the success of the Ninth International Medical Congress, recently held in Washington, we early copied the full and gratifying expressions of the London *Lancet* and the *British Medical Journal*, and in furtherance of the same object we now give the following from a good authority in Paris [1]

"We did not wish to take any part in the controversy that arose in the columns of the principal medical journals of Paris, on the subject of the *success*, or *non success*, of the recent Congress at Washington

"Some were enthusiastic over the importance of the work, and at the kind reception given to the foreign learned men Others found through the pen of their correspondents rather slight appreciation Newspapers of *rapid information* registered in succession the pro and the contra

"For every impartial mind, the accounts rendered of the sessions, which were sent to Europe through the obliging and disinterested care of the *Medical Record* of New York, bring perfectly to light the number and value of the daily communications and addresses in the general sessions Besides, these works are impressed on one with a novelty and originality not generally met with in Congresses of this kind

"As to all that is relative to the American customs, studied at the receptions in the Pension Hall and White House, one should have a little more indulgence for the large reunions of men, for without crossing the Atlantic, one could see the same actions, and analogous incidents (as at the shaking of hands with President Cleveland) being produced at the aristocratic Court of Vienna during the Congress of Hygiene, and, if it were permitted to recall the fact, at the ultra democratic receptions at the City Hall in Paris Therefore, away with the system of *two weights* and *two measures!*

"Besides, in a letter addressed to the *Medical Bulletin*, Dr Landolt praises very much, and with right, the reception that the learned Frenchmen received from their colleagues in America, not those in the middle of the tumult of a Congress, but in their hospitals, in their laboratories, even at the threshold of their activity The criticisms, modelled by a certain journalist in his "*Voyage of Study*," against Mr Hamilton, cannot attach to the eminent Secretary General of the Congress All our private correspondence, even that written by our American colleagues, who for personal reasons, abstained from taking part in the organization and working of the Congress at Washington, are unanimous in acknowledging that he maintained himself with credit under all the circumstances connected with the arduous task that he had accepted

"And we, that have the good fortune of knowing for a long time the intellectual activity, the exquisite politeness and presence of mind of our colleague of the French Society of Hygiene, are very happy over the impartial and generous appreciation of Dr Landolt, and let us conclude with the hope of seeing next, the important scientific works of Dr Hamilton rewarded with the title of *foreign corresponding member* of the Academy of Medicine of Paris "

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, June 1, 1887

THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

DR J FORD THOMPSON reported a case of

DEATH FROM SHOCK DURING AMPUTATION

He said that the unfortunate accident was the first of the kind that had ever happened in his practice, and while he was not proud of the termination, he would nevertheless report the case The patient was a man who had sustained a compound comminuted fracture of the leg just below the knee, about four weeks previous to his first visit, which was yesterday He did nothing at that visit, but called again this morning

He then found that the fracture was entirely ununited and that the soft parts were in a very bad condition, the thigh being infiltrated with pus up to its junction with the body He opened up some of the abscesses in the thigh and then went at once for his instruments in order to amputate, as no time was to be lost in performing an operation that would, in his opinion, give the man at least a small chance of life

Having made everything ready he proceeded at once with the operation, Dr Friederich administering the ether while Dr Cutts assisted him, there being besides the son and a friend of the patient in the room during the whole proceeding

Before beginning the operation Dr Friederich had called his attention to the fact that the man was taking ether badly, but as he had been given a good dose of whiskey there seemed to be no particular danger, so he went on With the intention of doing a modified Carden he made the anterior flap long and of skin, the apex of flap being over the middle of the patella The posterior flap was made from skin and muscle, and the femur was sawn through about 1½ inch above the condyles

At the first stick of the knife bloody pus gushed out from sinuses in every direction in the thigh The tissues on all sides were extremely friable and came off in great shreds and sloughs in his fingers Having performed the amputation he washed out the sinuses as well as possible, and stripped the femoral vessels, in their sheath, of the surrounding tissue He then opened the sheath and ligated the artery, putting also an extra ligature about ¼ in above the first The vein was then tied Upon removing the tourniquet there was no hæmorrhage from any source Long drainage-tubes were then put into the sinuses in the thigh and he was about to put in the sutures, when his attention was called to the low condition of the man, who was pulseless at the wrist and gasping for breath Having seen such conditions before he simply gave some whiskey hypodermatically, and proceeded at once to finish the operation While completing this the limbs were kept elevated and artificial respiration was kept up—the ether having been withdrawn some minutes previously

Having dressed the stump he turned his attention to the patient, who appeared to be sinking rapidly More whiskey and some ether were injected, while artificial respiration and other appropriate expedients were tried There was a revival of the respiration for a few minutes and the skin got warm, though the pulse never came back to the wrist In the hope of getting him to vomit, and thus stimulate the heart, he passed a catheter well down into the œsophagus and injected about two ounces of brandy and water into the stomach This did not succeed, however, and the patient went into collapse and died after having been worked on for over an hour The heart ceased a short time before the respirations

This is the first accident of the kind that he has ever had happen to him, and while in this case the man was in a wretched condition from the first, he had no reason to believe that a fatal termination would immediately follow the operation The ether had been administered carefully and not much had been given

DR J B HAMILTON said that he knew something about the case just reported, and would supplement Dr Thompson's statements He had been called to see the man the night of his accident, about four weeks ago He found a fracture just below the knee but he thought that it did not extend into the joint Amputation was advised at once, but his people would not permit it, and besides there was so much shock that he was the more willing not to do it The wound was then drawn as close as possible and the limb was swung in an apparatus He saw him a few days later and found him weaker than at first and much emaciated, though there had been no chill nor anything to indicate septicæmia He saw the patient a third time about two weeks ago, and at this visit he opened a sinus in the popliteal space and evacuated about a quart of pus He told the attending physician that the man would probably die whether his leg was amputated or not He heard nothing more of the case until Dr Thompson reported it

He thinks that Dr Thompson's patient died of shock—a not uncommon complication in such cases Three years ago a young sailor was admitted into the Providence Hospital with a compound fracture of the femur just above the knee-joint The accident had happened six weeks previously and the man was in a very low state, so that amputation was not thought advisable Suppuration of the wound was going on, so he was treated with small doses of the bichloride of mercury, and after a time he appeared to have recuperated some Suppuration continuing however, amputation was performed Not much blood was lost, and just after the removal of the limb he noticed that there was not the natural oozing of the parts The ether had been stopped The patient was in a state of collapse, and died in spite of every effort to save him Shock and pyæmia were probably the causes of death

DR J B HAMILTON gave the histories of

TWO CASES OF LITHOTOMY, WITH SPECIMENS, A CASE OF RHINOPLASTY, WITH PHOTOGRAPH

(See p 752)

DR J FORD THOMPSON said that the subject of the best way for the removal of vesical calculi was being very much discussed at the present time While his own favorite operation for small stones is the median perineal, he thought that the first stone exhibited by Dr Hamilton, being small and soft, might better have been removed by lithotrity (Dr H explained that the stone was encysted in the anterior wall of the bladder and could not have been reached by a lithotrite) Dr Thompson said that in that case, of course, his criticism did not hold good We have four principal operations for removing a calculus For his part, in the young, with a small hard stone, he prefers the median perineal incision It is true that this is objectionable on account of the impotence which may follow it, yet the operation is so successful in regard to mortality that it is being largely done

The great trouble with Bigelow's lithopaxy is that it is very difficult to completely evacuate the bladder after the crushing Even Thompson's evacuator, which is better than Bigelow's, is not perfect, so he has himself adopted the practice of inserting a large-size tube, filling the bladder with water and then letting the pieces of stone escape with the return current The operation is undoubtedly a valuable one, though it was said when supra-pubic lithotomy was introduced, that the days of lithotrity had passed

After performing lithopaxy upon a man who had had albumen in the urine for years, and having, as he thought, completely emptied the bladder of fragments, he put in a searcher and struck a piece of stone Being unable to reach it with the lithotrite, he did median lithotomy Within 24 hours the man had the most intense pain in the right knee with much swelling He opened the abscess and dressed it antiseptically, but the man died after a month, without, however, having had any bladder symptoms The trouble was pyæmia, which came on in 24 hours after the operation

At present von Dittel and Ultzman, of Vienna, teach that the supra pubic lithotomy is the only scientific operation It is certainly applicable when

there is a large stone, especially in children In old cases with large stone the bladder is apt to be contracted and hence difficult to reach from above This can in part be overcome by the water bag in the rectum In his opinion, while the supra pubic operation has become a well recognized one, it will never entirely take the place of all other operations, each of which has its particular sphere

Last week he saw a boy who had fallen and fractured the bridge of his nose seven years before No doctor had attended him at the time The nose was perfectly flat at the bridge, the vomer having been driven in and the sides crushed He considers this a difficult case to operate upon, as, before doing anything in this situation, we must be sure that we can at least benefit the deformity Plastic operations for the restoration of the nose are not, as a rule, very satisfactory when there has been much loss of tissue, though Billroth will remove the whole nose for epithelioma and make a very good substitute by the plastic operation

DR HAMILTON said that the results of the median lithotomy were certainly satisfactory so far as the immediate relief to the patient goes Bigelow's operation is unsatisfactory in some ways and is not applicable to children with narrow urethræ, while the supra pubic operation has had its rises and falls for many years As far back as 1867 he saw a surgeon do this operation

In removing the flap for the nose depicted he took up the periosteum with the skin, and when this flap was brought down the column was made from the periosteum The nostrils were kept open with tubes, while the nose was moulded by the ordinary dough method

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, October 6, 1887

THE PRESIDENT, THOMAS M DRYSDALE, M D , IN THE CHAIR

(*Continued from page 725*)

DR M PRICE reported a case of

ADHERENT INTESTINES FROM PERITONITIS, SIMULATING FIBROID TUMOR

Mary J , colored, æt 17 years, received a kick in the belly from a horse, about eighteen months ago She was confined to her bed for a number of weeks and was a confirmed invalid up to the time of operation, suffering great pain in the lower part of the abdomen, the region of the injury She was unable to work or do anything towards her own maintenance Upon examination a hard mass was found high up and to the right of the uterus Owing to her condition and the repeated efforts for her relief, it was decided to open her and see if the offending cause could be removed I opened her, June 17, 1887, Drs C Penrose and J Price assisting, and Dr Welsh present The bowels were found completely matted together, with an ill defined mass at the right side Nothing was found that could be removed The omentum could not be found Dr J Price suggested the separation of all the old adhesions of the bowels, peritoneum and mesentery, which I at once proceeded to do These adhesions involved the entire length of the small intestine, binding the folds of the mesentery and knuckles of intestine in one solid mass The adhesions were of such strength that many of them had to be cut through with scissors The scissors, hand and sponge were the instruments used in the separation of the adhesions This method was followed until every knuckle of intestine and fold of peritoneum and omentum was separated The bowel was almost completely occluded by the bands Complete irrigation with distilled water at a temperature of 110° was used After this operation was completed the indurated mass could not be found She reacted well and was freely purged with Epsom salts She made an uninterrupted recovery, and said she had less pain the day after operation than at any time after the kick I have seen her frequently since the operation She is perfectly well and able to be about her work As a distinct surgical procedure I know of no similar case on record I opened a man a year ago for great pain in the region of the gall bladder, and tore open the adherent viscera from the abdominal wall so as to complete my examination, but finding nothing wrong, closed up the incision The pain was cured! But this operation was not performed with the same object in view as in the first case Dr Duncan, in his book on "Diseases of Women," p 49, gives a case in point I remember a case diagnosed as a fibroid tumor of the uterus, a hard rounded mass as big as a child's head, above the brim of the pelvis, very tender and slightly fixing the uterus The young lady died, and at the post mortem examination it was found that there was no fibrous tumor at all It was adhesive perimetritis, a pocket of coherent intestines, which formed a hard mass and had led to the deception of eminent and experienced gynecologists "

DR M PRICE also reported a case of

SPINDLE CELLED SARCOMA OF THE OVARY

Mrs M , æt 44 years, married twenty years, sterile, always regular, had always enjoyed good health up to January 1, 1887, when she was greatly troubled with inability to hold her water and with constant pelvic pain, with a feeling of fulness and an entire suppression of the menstrual flow, which had been regular up to that date The incontinence of urine was relieved about the middle of February by the escape of the tumor into the abdominal cavity The tumor grew rapidly, and when it had reached some two inches above the umbilicus the patient thought she might be pregnant and sought advice as to her condition Upon examination I found the uterus small the left ovary and tube healthy and posterior to the tumor The right ovary could not be found, but in its position the pedicle of the tumor could be mapped out The removal of the tumor was advised Operation June 11, 1887, with assistance of Drs J Price, Burns and Penrose A spindle celled sarcoma of the ovary, weighing 5 lbs , was removed The

patient reacted well On the evening of the second day there was a slight rise of temperature and quickening of the pulse Fearing peritonitis, I ordered a tablespoonful of Epsom salts every two hours until the bowels were freely moved Six doses were given The next day the pains had disappeared and temperature was normal She has made a perfect recovery

DR DRYSDALE remarked that the successful result of the operation in this case was a proof of its justifiability, but he thought that, generally speaking, it would be of doubtful advantage to perform abdominal section for the relief of the consequences of peritonitis, as adhesions would be likely to reform immediately after the operation

DR PRICE explained that the active movements excited by the Epsom salts prevented new adhesions from forming He made some remarks on ovarian tumors and stated that, although seeming to be of fibroid character and called fibroid at time of removal, microscopic examination had, in his experience, uniformly shown them to be spindle-celled sarcomata

DR PARISH remarked that it is always allowable to break up inflammatory adhesions in abdominal operations The new adhesions formed are not firm

DR H A KELLY, a year ago, had examined a small tumor, about the size of a pea, distinctly arising from the ovary, and found it to be a fibroid, it was quite hard He had, three months ago, removed from a girl of 11 years a large sarcoma of the ovary She recovered The intestines might be bound together into a mass by plastic lymph, and if there was no unnatural position of any portion, no kinks nor strangulation, no symptoms would be developed The patient would feel no pain and would be conscious of nothing wrong In an operation all bands and local adhesions should be broken up, and kinks or knuckles should be liberated

DR J PRICE said that trouble will sometimes follow breaking up of old adhesions in the removal of cystoma, local pain and alarming local and general symptoms He thinks the matting together of the intestines resulting from general peritonitis a cause of death in some few cases, and could be averted by prompt surgical interference He described a case which he had seen recently as consultant, and in which he advised immediate operation The attending physician would not consent until he thought his patient dying from peritonitis The abdomen was now opened and the pus and lymph removed by irrigation and sponging, all adhesions were freed, and the patient commenced to improve immediately, and is to-day a well woman The operation was the only way in which her life could be saved In his brother's case the intestines were freed by free dissection, pressure was applied afterwards to hold the intestines back in the loins and keep them immobilized The hæmorrhage during these operations was very slight Dr J Hoffman had in a recent operation in which Dr Price assisted him, found fourteen inches of the large intestines adherent in an operation for the relief of an umbilical hernia, requiring a long and masterly dissection If such adhesions are not liberated, the operation of dividing the stricture and simply liberating the strangulated portion may be a failure in saving life Here again Mr Tait, in his deep surgical wisdom, recognizes the importance of opening the abdomen for strangulated hernia in the median line, that inflammatory adhesions and strictures may be liberated in the most scientific manner Adhesions in pelvic inflammations are very common, and in operations they should always be released Hard bodies are frequently discovered in the tubes and ovaries Their appearance suggests fibroid growths, but they are in reality sarcomatous The round ligaments alone do not seem liable to disease

DR MONTGOMERY was very much interested in the subject of this paper The method of first breaking up the adhesions and then preventing their reproduction by peristaltic motion excited by saline purgatives, is similar in principle to the treatment of anchylosis in joints, breaking up adhesions and passive motion subsequently Doubtless all present can bear witness to the beneficial action of saline laxatives in dysentery and other inflammatory intestinal affections He had recently assisted Dr Warder in the removal of an abdominal growth The diagnosis had been interine fibroid, but when the abdomen was opened the tumor was found to be of ovarian origin It was very large and hard Dr Daland had made an examination of it and reported it to be fibroid in character There was considerable ascitic fluid

DR LONGAKER made some remarks on the clinical history of adhesions Some months ago, the specimens from a case of obstruction of the bowels ending in death were shown by him at the Pathological Society This was a case of encysted, retrouterine hæmatocele, the appendages on both sides being involved in the mass of adhesions, from which there passed a band to the lower portion of the descending colon about nine inches above the sigmoid flexure, where it was so attached as to form an acute flexure At this point the bowel was in a gangrenous state and the colon above was greatly distended, while the portion below the obstruction had a lumen just admitting the passage of the little finger The patient manifested no symptom of difficulty until four or five days after labor, when some nausea and vomiting occurred The points of interest are that while the autopsy demonstrated the feasibility of an operation, the symptoms were at no time sufficiently definite to warrant a diagnosis The patient must have had the trouble a long time without its giving rise to any but vague and indefinite symptoms As involution of the uterus took place this knuckle of bowel was slowly dragged down into the pelvis

DR M PRICE, in closing, said the appearance of his first described patient was remarkable The long continued suffering from peritonitis had so wasted her that she looked as if she had been passed through a wringing machine, her chest and belly were flattened out If no symptoms resulted from the adhesions there would be no call to operate for their relief But in all cases the intestines have sharp bends and curves, and form knuckles which are caught under lymph bands which tie the intestines together and contract them, and sooner or later symptoms of obstruction must be developed He

does not believe in antiseptic surgery as applied to the abdomen and the peritoneum If he did believe in microbes, tadpoles and the other insects so much talked about, he would be afraid to operate, for their presence, if all that is said about them were true, would do more harm than the peritonitis and more than the operation would do good

DR W H KELLY considered this a most important subject, and one on which we are greatly in need of enlightenment His own experience had taught him several interesting facts in regard to peritoneal adhesions Bands of adhesion or the adhesion of a small area of intestine in such a way as to make it liable to kink, doubling it sharply on itself, are exceedingly dangerous and should never be allowed to remain But there is a class of adhesions by no means dangerous, not productive of symptoms, and which should not be interfered with We must bear in mind that the adhesion of opposing serous surfaces is a conservative process, preventing the continuous pouring out of effusion, and in event of tuberculous peritonitis probably starving out the disease by taking away its pabulum The least dangerous variety of adhesion is the general adhesion of the gut *in situ* He operated two years ago on a case in which all the intestines adhered, looking like one great bag when the peritoneum was opened It was a case of tubercular peritonitis tending to a cure in this way I simply dried out the peritoneum and besprinkled it with iodoform to check secretion, and the patient, who has been constantly under my eye ever since, has had no trouble from her adhesions Also those cases of adhesions of lesser intestines in the pelvis, in which they lie adherent in normal relative position, in full round curves without kink, do not, so far as I have been able to observe in a large number of cases, ever do harm

(*To be concluded*)

PHILADELPHIA COUNTY MEDICAL SOCIETY

THE PRESIDENT, J SOLIS-COHEN, M D, IN THE CHAIR

Stated Meeting, November 9, 1887

DR SOLOMON SOLIS COHEN read a paper on

LAVAGE IN THE TREATMENT OF GASTRIC AFFECTIONS

(See page 745)

DR J TYSON said I have had some experience with lavage, although I have not employed it in the last ten years In one case of dilatation of the stomach it was used with a great deal of comfort to the patient He learned to introduce the tube, would wash out his stomach, and enjoy a good meal afterward He subsequently passed from under my observation, but I heard of his death, which was, I believe, due to the disease which had caused the dilatation—cancer of the pylorus In a second case in which I employed it, the result was not so satisfactory, and it caused great discomfort

DR W OSLER said I should like to state my experience in the use of irrigation, as this is a measure in which I have been interested for several years In the first place, there is serious objection made to the procedure by at least one half of the patients, on account of the discomfort experienced in the introduction of the tube The soft tube is sometimes very difficult to pass, and sometimes it is necessary to resort to the stiffer tube Where the patient himself performs the operation, it is, of course, better that he should have the soft tube

I am of the opinion that this measure has a much narrower field than the statements of the French and German writers would lead one to infer I should not hesitate to predict that within a few years, when the fashion has subsided, this measure will be confined entirely to cases of obstinate gastric catarrh in which it is of inestimable service, and to cases of dilatation of the stomach, in which it is not only of service, but absolutely indispensable We have no satisfactory treatment for dilatation of the stomach other than irrigation

DR E MARTIN said During my term of service at the University Hospital, this method of treatment was introduced by Dr William Pepper, but our experience was, as Dr Osler has stated, the patients would not remain The measure was tried in six or seven cases, and all but one left The patient who remained experienced marked benefit, he gained in weight, and when he left the hospital six months later, was able to pass the tube himself The difficulty which I have recently experienced in one case is, that the patient would vomit the tube This I overcame by using a stiffer tube

DR J P C GRIFFITH said During the past year I have been much interested in lavage in the diagnosis of diseases of the stomach, the German medical papers having been full of the subject We, in America are, however, unable to study the matter to any great extent, owing to the rebellion of patients to this method of examination German patients appear to be more tractable, and Riegel reports that during the year 1885, he made over 1300 examinations of the gastric juice in 122 cases, and in 1886, tested 134 cases in a similar way Every patient presenting evidences of disease of the stomach was submitted to lavage, and the gastric contents thus obtained were subjected to a chemical examination Riegel's method is to administer to the patient an ordinary mixed meal, and, after about six hours—the stomach should be empty at the end of seven hours—to remove the gastric contents, if possible, undiluted by the employment of water, and to filter them He then tests the filtrate in order to determine especially the presence or absence of hydrochloric acid, and the peptic strength The tests are at once simple and very delicate He employs a variety of these, but the ones which have proved most satisfactory to my hands, and with which I feel most familiar are the reactions with methyl violet and Congo red for hydrochloric acid, and Uffelmann's carbolated iron test, for lactic acid In the presence of a small amount of free hydrochloric acid a dilute solution of methyl violet will turn to a blue color, and Congo red will also be

that the subsequent history of the fœtus is one merely "of development, its attachments merely for nutrition and shelter"

Allow me here to commend to your consideration a small volume, of about 200 pages, upon "Criminal Abortion, its Nature, its Evidence and its Law," by Dr Horatio R Storer The collection of evidence and statistics showing the prevalence of this crime would astonish those who have not given especial attention to the matter, even members of the medical profession I am indebted to this writer for some of the conclusions here presented I would call attention, also, to the fact that our statute also makes makes it a penitentiary offense to advertise or cause to be advertised, or in any manner call attention to or recommend any drug, nostrum, or instrument to be used in the perpetration of this crime The law is ample, Shall it be enforced and its violators brought to justice?

The changes in the law as indicated by the difference in our statutes at other times, are simply the formal legal expression of the changes in public opinion And after all that has been, or may be said by way of criticism, in regard to adherence to precedents, you will find that the laws upon this, and all similar questions, arises to the same moral plane of right and wrong occupied by the people by whom, and for whose benefit and protection, it is enacted It is not the production of abstract theorists It is the essence of human judgment, the concrete of human experience

The question then very naturally arises, if this be true, and with the alarming frequency of the violation of this law, why is the law so rarely enforced—its infraction so rarely punished? In answering this question, the fault or neglect cannot be attributed to any one cause, or any single class in the community There are numerous reasons, among them are secrecy surrounding the act, the lack of moral conviction in the minds of many of the participants, the general absence of all fear of detection, the prevailing of a feeling of "false modesty," the number of persons practicing as physicians who will commit the crime, or contribute towards its commission, and the sacredness of the professional confidence of the regular physicians Honorable practitioners owe it to themselves and to their brethren to drive from the public mind the too prevalent opinion that *money* will induce almost any physician to perpetrate a crime against the laws of God and man

Of the mother, by consent, or by her own hand imbrued with her infant's blood, of the equally guilty father, who counsels it or allows the crime, of the wretches, who by their wholesale murders far out-Herod Burke or Hare, of the public sentiment which palliates, pardons, and would even praise this so common violation of all laws, human and divine, of all instinct, of all reason, all pity, all mercy, all love, we leave those to speak who can

DR SAWYER wished to correct Dr Steele in regard to the frequency of criminal abortion He quoted Cazeaux and La Chapelle as saying that abortions in Paris as were common as labors at term He, himself, had never seen one-tenth the number of abortions hat he had of labors

DR HENROTIN said he had in former years many opportunities to investigate cases of this character He had had the pleasure of bringing several of these criminals to justice, and had been instrumental in sending two of them to the penitentiary The crime, he said, was a very common one Several cases of physicians and others who had been guilty of the offense were mentioned and suggestions as to conviction

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT.)

Urethral Calculi—Multiple Calculi—Displaced Calculous Kidney

At the November meeting of the New York County Medical Association some remarkable cases of stone were presented The first was presented by Dr Daniel Brown, who said that the patient, a man 61 years of age, came to him complaining of inability to pass his urine The penis was unusually small, and finding that the meatus, which was of very narrow calibre, was occluded with some hard substance, Dr Brown incised it and removed several calculi After this he practiced gradual dilation of the urethra until a number 18 sound could be passed, and at no time during the process of dilatation was there any evidence presented of stones in the bladder From this time the patient had no further trouble until the end of two years, when he again presented himself suffering from stoppage of urine Calculi were once more found blocking up the urethra, and every day for a considerable period some were removed On one occasion, in endeavoring to get into the bladder, his assistant was unfortunate enough to make a false passage There was marked cystitis, and the patient gradually sank After death the bladder was found to be full of calculi

The question naturally arose, Was this a large stone which had spontaneously ruptured, or were there originally a number of small stones which formed in the kidney and afterwards received accretions in the bladder? The shape of the calculi seemed to indicate that the former was the correct hypothesis, and this was also rendered the more probable by the complete absence of renal colic during the history of the case

The bladder of the patient, that has not as yet been opened, was now presented by Dr J W S Gouley, to whom Dr Brown had transferred it for preservation in the museum of the New York State Medical Association Remarking that to the touch the organ felt like a bag filled with coarse gravel, he laid open its cavity with the knife, when it was found that the walls were somewhat thickened, though not to such an extent as might have been expected under the circumstances The calculi which it contained reached to the upper fundus, and on emptying them out he found that there had been a spontaneous fracture, not of a single large stone, but of a number of smallish stones, the greater part

of which had been too large to be expelled spontaneously There was, however, no urethro vesical obstruction, such as would have been caused by an enlarged prostate, and there was, therefore, no reason why some of them should not have been discharged in this way The mucous membrane was found to be more or less columnar, and in it were a number of little pouches One of these was large enough to admit the end of the little finger, and at this point there was some ulceration of the membane

This, then, Dr Gouley said, was a case of multiple calculi, and it was one of very puzzling character Many explanations had been offered for the spontaneous fragmentation of large stones in the bladder, and there was, indeed, scarcely an authority in this department of surgery who had not brought one forward But in the present instance not one of them was applicable, and he was quite at a loss how to account for the condition of affairs met with Taking up a number of the pieces, he said that he held in his hand no less than eleven distinct nuclei, and that there was not a single entire stone in the mass found in the bladder, which would weigh over a quarter of a pound The extraordinary feature of the case was the spontaneous rupture of all these stones

Dr J R Mac Gregor then related a remarkable case occurring in his practice some years ago The patient, was a lady of 63, who came to him stating that she had had a great deal of pain for a long time in the hypogastric region, and bringing with her a box containing more than 300 calculi that she said she had voided from time to time A vaginal examination revealed the fact that a number of calculi could be felt with the fingers, apparently in the bladder A further examination was made at her own house, when gradual dilatation of the urethra was accomplished with sounds, and a narrow bladed pair of forceps introduced into the bladder Nothing like a stone, however, could be detected, and this attempt gave rise to so much pain and distress that the patient declined any further interference for the time being

She then went out of town for the summer, but by the time that she returned her sufferings had increased to such an extent that she was willing to submit to any procedure that promised relief The late Dr Studley was called in consultation, and ether being administered, the urethra was gradually dilated until the finger could be introduced into the bladder No calculi were found loose in the latter, but plenty of them could be felt covered, apparently, with some sort of a membrane, and it was concluded that the calculi were encysted With the finger nail and a pointed instrument the supposed membrane was ruptured, and two calculi, each about the size of a grain of corn, were extracted The others that were felt receded beyond reach when the effort was made to get at them The discovery was then made that there was also a stone present of very large dimensions, but it was deemed imprudent to attempt anything further on this occasion The patient had taken ether very badly, so that at one time it was necessary to resort to artificial respiration and hypodermic injections of brandy, and she died in about forty eight hours

At the autopsy there was found in the pelvis, an organ resembling the uterus at the fifth month of pregnancy, and on section there was discovered in it a stone of enormous size, together with a very large number of small ones, This organ proved to be the left kidney, that had become displaced and occupied the ordinary situation of the bladder It was flattened out like a large sac, and in it were found more than 520 calculi, while some additional ones were lost in the abdominal cavity The large stone that Dr MacGregor presented was somewhat pear shaped, and weighed no less than 51 ounces It was 6⅜ inches long, and measured 16⅝ inches in its larger circumference, and 12½ inches in its smaller circumference At each end there was an area where the surface had become polished from contact with the small stones- A section of the mass has never been made, but it is supposed to consist mainly of uric acid, although the exterior is thoroughly encrusted with earthy phosphates Dr Mac Gregor then proceeded to refer to some of the cases of unusually large stone reported by various authors, and in conclusion said that with the exception of one that Lister came across in a journey to Paris, the stone now exhibited was the second largest on record

Dr Alfred L Carroll having said that he could not see how the phosphatic coating of the stone could be accounted for unless there had been an opening between the kidney and the neck of the bladder, Dr Gouley stated that he had become convinced from repeated observation that phosphatic deposits frequently occurred in the pelvis of the kidney, and that they might take place in any part of the urinary apparatus In herbivorous animals it was a well known fact that the kind of stone which ordinarily originated in the kidney was the phosphate of lime calculus P B P

DISINFECTION OF GYNECOLOGICAL INSTRUMENTS

Dear Sir —The article of Dr French on the "Chief Source of Danger in the Use of the Uterine Sound," in the August 27th issue of THE JOURNAL, is timely and valuable, yet I cannot let the occasion pass without criticising one point Fritsch is quoted as saying "Always before introducing the uterine sound, dip it into a 5 per cent solution of carbolic acid, even though properly cleaned directly after its previous use "

I do not claim that the single dipping of a sound into a 5 per cent solution of carbolic acid may not prevent septic infection, but from my observation of the manner in which the common gynecological outfit is kept, I can safely assert that either a grinding or polishing would be necessary to remove the incrusted dirt from many sounds As a matter of fact, the method of Fritsch is entirely inefficient as an antiseptic measure The best way to disinfect all gynecological instruments not tempered for cutting purposes, (curettes, placental forceps, sounds, etc ,) is to pass them several times through the flame of a spirit lamp, and then place them in a so-

lution of carbolized water From this solution they should be taken and used, without coming in contact with anything not rendered thoroughly aseptic This efficient and *absolutely reliable* means may also be applied to the instrument used for exploring the bladder

The remarks of Dr French apply with added force to the use of tents of whatever variety Indeed, the dangers from this source have become so great, that many practitioners have discarded tents altogether, though theoretically they should be much less dangerous than divulsion or incision For the past two years I have been specially studying the uterine reflexes, and have had occasion to use the sponge-tent frequently I have thus far escaped the slightest inflammatory reaction or septic infection from their use I am satisfied that the only danger from the use of tents is their liability to convey septic matter They are of a porous material, usually kept loose in a box, or in the physician's obstetric bag, or on his table in the neighborhood of decaying urine, pathological specimens, etc It is surprising that septic infection is not more frequent

My method is to place the tent in a small vial, just large enough to contain it, the neck is filled with absorbent cotton and a cork fitted The bottle is then placed in an ordinary bake oven for one or two days The heat is, of course, sufficient to destroy all germs, and as they cannot obtain ingress, you have a thoroughly aseptic tent, which may be used at any time When introducing them the vagina should first be thoroughly irrigated with a corrosive sublimate solution, and the neck of the uterus wiped out with carbolized glycerin The cork is then removed, and the tent is grasped in a pair of sterilized dressing forceps and introduced A cotton tampon saturated with carbolized glycerin completes a procedure which, if efficiently carried out, will, I am sure, make infection from the use of the sponge-tent a thing of the past

Very truly yours,

HAROLD N MOYER, M D

CASE OF HYDATIDIFORM MOLE

Dear Sir —In the issue of THE JOURNAL of November 26, Dr Thos C Smith, of Washington, D C , reports two cases of "Hydatidiform Mole " As I also met with a case a short time since, and in many respects similar to the last of his cases, I beg to submit it to the profession

Mrs W , æt 41, white, has had six children *Previous history* —Several years ago, she tells me her old family physician, now deceased, treated her for "falling of the womb" by introducing a support, but since he died she has used nothing, and has had no trouble until recently, when she called me in, complaining of pains in the back and side, profuse leucorrhœa, and a general feeling of fatigue I advised an examination and an introduction of the proper support, but for various reasons it was postponed She incidentally mentioned that her monthlys had not then appeared for two months Pregnancy was at once suspected, but she persistently denied that such was the case, saying that in her other pregnancy she never felt as she did then I then advanced the idea that the "change of life" was coming on her, but was still suspicious of pregnancy

About a month afterwards I was hastily summoned to her bedside, the messenger saying she was "flooding " On my way there I learned that she had done an unusually large day's work that day, and while she was at the supper table she had suddenly begun to bleed On arrival at the house I found her pale, weak from the loss of blood, and all with the symptoms of previous profuse hæmorrhage An examination was made and revealed an enlarged womb, of about three months' pregnancy, and very painful to the touch, os dilated so that my index finger passed in with some difficulty Hæmorrhage profuse Of course a miscarriage was at once diagnosticated, and the proper treatment of rest in the recumbent posture, opiates and ergot were given, and the patient left for the night The next morning she was still bleeding but not so freely, os and womb in about the same condition The same treatment was continued, and a tampon of cotton applied, and retained for fifteen hours, when it was removed, and I found a handful of hydatidiform bodies in the vagina, and a large piece of what looked to me like placenta was removed from the womb, after which she ceased bleeding and made a rapid recovery She still claims that there was nothing wrong with her, and that she was not *enciente*

Very Respectfully,

J S HACKNEY, M D

Uniontown, Pa , Dec 1, 1887

EHRLICH'S TYPHOID-URINE TEST

Dear Sir —In No 2, vol IX, p 53, of THE JOURNAL, you print what is meant to be the formula for Ehrlich's test of typhoid urine, of which I spoke in May last, before the Association of American Physicians, in Washington In your communication, as also in those of many other journals, there was a serious typographical error, that ought to be corrected in the interest of Professor Ehrlich, but still more so in that of many of your readers The formula is as follows

1 Sodium nitrite, 1 part, aq destill , 200 parts (is liable to be decomposed after from four to ten days)

2 Acid sulfanilic, 5 parts, ac hydrochlor conc pur , 50 parts (not 5), aq destill , 1,000 parts (not 100)

Of 1 take 1 2 parts, of 2 take 50 parts, to form 3

Mix 3 and urine in about equal quantities, and add slowly aq ammon towards neutralization The deep maroon color will soon appear I advise to test normal urine first, or alongside the suspected or morbid specimen Very respectfully,

A JACOBI, M D

110 W Thirty fourth St , New York

NECROLOGY.

R W HOOPER, M D

Robert William Hooper, M D, of Cambridge, Mass, was born in Marbletown, Mass, Oct 25, 1810, died at his residence April 13, 1885 He was the son of John and Eunice Hooper He graduated in letters at Harvard College in 1830, and in medicine in 1836 After having studied some years in Europe, opened an office for practice in Boston In 1837 he married Ellen Sturgis, daughter of Wm Sturgis, merchant of Boston His wife bore him three children and died Nov 3, 1848 The children survive their father Dr Hooper was for many years one of the surgeons of the Massachusetts Charitable Eye and Ear Infirmary For thirty years he was one of the trustees of the Boston Athenæum And for nearly the same time he was connected with the State Hospital for the Insane, at Worcester, of which he was a trustee He was a member of the Massachusetts Medical Society, and also the American Medical Association J M T

RUFUS WOODWARD, M D

Rufus Woodward, M D, son of Dr Samuel B Woodward, who was so distinguished as the first physician of the first State Lunatic Hospital in Massachusetts—the one at Worcester, was born in Weathersfield, Connecticut, Oct 3, 1819, and died at Worcester, Dec 30, 1885 He graduated in the classical department at Harvard College in the class of 1841, and received his degree of M D in the medical school of the same college in 1845 He served as assistant to his father in the Lunatic Hospital, and to Dr George Chandler, who was his father's successor for about five years Resigning this position in 1848, he went to Europe, for further prosecution of study, mostly in Paris, for two years, when he returned to Worcester, and entered upon general practice, which he continued up to the time of his death, visiting patients even to the last day of his life

Dr Woodward held the respect and affection of his patients in an unusual degree, and never failed to deserve their affection and respect, and his professional assistants were even his best friends In his undergraduate course at Cambridge, President Walker took a special interest in him, and wished him to study theology But Dr Woodward was very fond of Natural History from the first, and he preferred the study of medicine, which was akin to it He loved botany especially, as if it were nearer to the Heavenly sunshine

He was one of the original members of the Worcester Society for Medical Improvement He was a founder of the Worcester Natural History Society under the counsel of the first Agassiz A member of the American Antiquarian Society, in one of whose recent publications there is an extended notice of him He was President of the Board of Health, and very efficient In all these offices he was faithful, and his merit was recognized, and resolutions of condolence and of respect on his decease were presented to the family, and spread on the records of the various organizations He was also a member of the American Medical Association since 1880

Dr Woodward was generous by instinct and by cultivation He was always happy, and happier when doing good to others He had no meanness, no malice, and no jealousies And in his death every member of the profession in his neighborhood, felt that the loss was of a good friend and a good man Dr Woodward was married June 12, 1856, to Jane N Fox who survives him They had four children, all of whom are living The oldest, a son, succeeds to his father's practice T S

BOOK REVIEWS.

THE CURSE OF THE WORLD, NARCOTICS Why Used, What Effects, the Remedy With numerous Colored Illustrations By DANIEL WILKINS, A M, Superintendent of the Washingtonian Home Chicago The Blakely Printing Company 1887

This is an octavo volume of 370 pages, published in most excellent style But the attractive features imparted to the volume by the skill of the publishers, affords only a faint index of the remarkable value of its contents The author is a man of high moral and intellectual endowments, of perfect candor, who has devoted forty years of his life to the practical work of reclaiming men from intemperance with a patience, intelligence, and success that has rarely been equaled During the last thirteen years he has been Superintendent of the Washingtonian Home of Chicago, an asylum for the reformation of inebriates, during which he has been brought into intimate personal contact with more than 6,000 inebriates, including almost every variety of intoxication, illustrating every degree of moral, intellectual and physical evil produced by alcoholic liquors and opiates, and has studied the motives, impulses, and needs of each from day to day, with that kindly spirit and earnest interest in their welfare that seldom fails to give him access to their fullest confidence Consequently the views presented in the book before us are the direct result of long continued practical study of the subject, with an ample field for observation The first division of the work discusses, in the most simple and interesting manner, the true influences, motives and impulses that lead to the use of fermented and distilled drinks or opiates, the second illustrates with equal clearness the effects of these agents upon the mental and physical conditions of those who use them, including several neatly executed plates representing actual important pathological conditions, and the third discusses the remedies with a logical directness, fullness of detail, and earnest, loving spirit that will not fail to carry conviction to the mind of every intelligent reader We wish the book could be carefully read, and re read, by every young man in our country

MANUAL OF CLINICAL DIAGNOSIS By DR OTTO SEIFERT AND DR FRIEDRICH MULLER Revised and corrected by Dr Friedrich Muller Translated by WM BUCKINGHAM CANFIELD, A M , M D 8vo, pp 175, with 60 Illustrations New York G P Putnam's Sons 1887 Chicago W T Keener

This little book is what its name signifies, a manual of *clinical* diagnosis It is not limited to the narrow field of physical diagnosis, but considers all that pertains to symptomatology It is without doubt one of the very best books devoted to this subject We have been led to expect of German writers a very diffuse treatment of this subject, but the book before us creates pleasurable surprise at finding it a model of compactness and detail This constitutes one of its chief advantages In reading it we have been constantly more and more pleased with the information and at the way in which it is told us Some statements we would like to see modified, but they are not of prime practical importance For instance, of Curschmann's spiral threads in sputa the authors say they "are observed in capillary bronchitis and bronchial asthma " To be sure, they occur oftenest in these diseases, but also frequently in pneumonia and sometimes in phthisis The sphygmogram is not described with as much fullness as we should like to see And thus a number of minor defects might be pointed out

The fact that in Germany it has already passed through three editions is evidence of its popularity

A MANUAL OF MEDICAL JURISPRUDENCE for the Use of Students at Law and of Medicine By MARSHALL D EWELL, M D , LL D , Professor of Common Law in Union College of Law, Chicago (Law Department of the Northwestern University) Boston Little, Brown & Co 1887

This is a small sized octavo volume of 409 pages, published in good style It includes a brief discussion of most of the topics usually presented in larger works on medical jurisprudence, with so much accuracy and good judgment as to make it an exceedingly convenient manual or text-book for students of both law and medicine Its value is much increased by numerous references to authorities and illustrative cases The author is well known as the writer of several valuable law books, and as an experienced teacher in the Union College of Law, to which he has added a regular education in medicine, thereby acquiring peculiar qualifications for the production of the volume before us

COURIER REVIEW CALL BOOK Arranged by E M WILSON, M D , Ph D J H Chambers & Co St Louis, Chicago, and Atlanta

THE MEDICAL NEWS VISITING LIST for 1888 Philadelphia Lea Brothers & Co ,

We are reminded of the rapid approach of a new year by the appearance of these well known and useful pocket visiting lists and account books Besides the blank pages there are in each a considerable number of printed pages, containing useful information that all physicians need and that often for the moment slips one's memory

THE MEDICAL WORLD VISITING LIST Being a Daily Record of Practice and Accounts without the use of Signs, and hence need no Transferring, arranged in Removable Tablets Published by *Medical World*, Philadelphia

This little book is novel and, we should judge, very convenient because of its small compass Each page is divided Each half is assigned to a patient At the top of the column the name and address are to be entered, and below on each line is the day of the month, and opposite it space to enter character of service and its value One column will hold all the entries for a month

SYPHILIS By JONATHAN HUTCHINSON, F R S, LL D , etc Sm 8vo, pp ix, 532 With 8 chromo-lithographs Philadelphia Lea Brothers & Co Chicago A C McClurg & Co

This is one of the publishers' "Clinical Manuals for Practitioners and Students of Medicine" We feel that Mr Hutchinson needs no introduction to the profession in this country, especially when he writes on syphilis As a clinical exposition of its subject, from the author's standpoint, the book leaves nothing to be desired The colored plates are well executed

MISCELLANEOUS.

DEATH OF DR T R VARICK —Dr Theodore R Varick, of Jersey City, died in that city on November 23, aged sixty one years He received his degree in medicine from the New York University He was well known as a skilful surgeon, and was Surgeon General of New Jersey for seventeen years

SPONGE-GRAFTING

Read before Section on Dental and Oral Surgery, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY WM H ATKINSON, M D,

OF NEW YORK

To intelligently understand the advantage of sponge grafting in efforts to secure reproduction of tissues, the societary arrangements among prime elements which lay the foundation of possibilities in functioning bodies must be taken into account Adequate study of these elements will reveal whatever pertains to them in personality and behavior Their origin cannot be seen, and their existence is provable to sensuous cognition only by observation of their aggregative and relational changes Therefore, to say they had beginning is to assume an unprova ble proposition The careers through which they go in molecular, corpuscular, tissual, organic and systemic currents constitute the functions of perceptible body

The first perceptible current is gaseous diffusion, which occurs in mass of diverse gases devoid of active affinity between them, each acting upon its own law of diffusion in occupancy of the chamber limiting the gas, so that each molecule stands equidistant from its fellows, which is known as "Avogadro's law" All diffusion of this sort is a mass motion rather than a molecular activity

The molecular action consists strictly in the formation of molecules and their disruption and reform ation in simple and complicated examples of mole cules, aggregations of which constitute proximate principles

The primal examples of molecular genesis is exhibited in the formation of water, H_2O, in which the diffusion of the two gases is limited to exact chemi cal equivalency of univalence and bivalence of the gases, interpenetrating each other with such intensity of thrust grasp as to produce liquid molecules of the new body, occupying only a fraction of the space the gases filled, leaving in the chamber (now empty of water molecules) only such H or O as found no mates in chemical equivalency When the oxygen is in such excess of the hydrogen as to afford the exact quantity, we have H_2O_2, or peroxide of hydrogen formed, as a distinct new variety of molecular body of less intensity of combining grip than that forming water This affords ready means of oxidation and hydration when hungry bodies are within the sphere of awakening currents of kindred energy

The results of these associative currents give us the bodies naturalists have classified as members of the three kingdoms, as the statical testimony to the typical form of the currents in chemical, physiological and mental movements in consciousness, the measures of which are displayed in protista, pro tophyta, protozoa, and their classified degrees in molusca, invertebrate and vertebrate forms of planetary inhabitants

Interpenetration or diffusion of gas, then, is the first form of feeding within the domain of bodies inhabiting planets, which planets are but masses of stored radiance with some unsatisfied bonds of desire for societary communion, the demand for which is known as hunger The comprehension of desire for more than the individual is conscious of having in possession involves a deep and intricate examination to so formulate it as to command the attention and kindly consideration of those who regard themselves as learned scientists Atomic, interatomic, molecular, inter molecular, gaseous, intergaseous, aqueous, inter aqueous, celloidal, intercelloidal, and solidal and inter solidal impact and diffusion of the impacted energy are the examples of caught and stored radiance upon which all functionable bodies depend

Personality of being (entos) must be accepted and comprehended if we expect to master career of function and factor of function The word person itself bears testimony to its origin as the initiative movement *in esse* producing existences (existere) *Per*, through, and *sonare*, to sound, are the mother and father of the word person Tone, then, is the measure of the stretch of intention limiting modes of consciousness in individual and associate presence in primal, proximate and ultimate forms of personal *Presence* I am aware that this layout starts at an hypothetical assumption of the primal body named atom with static and motic possibilities but does not state the dependence of atoms upon Infinite Substance filling space called ether, the impact of energy from which either communicates the combining and separative power to the atom or awakens latent capacity of career belonging to it

Taking this last statement into account etheric and inter-etheric currents are brought to view as intention, extension and limitation of type of bodies

in conscious formative procession Let us ask *what* and *how*, rather than *who* and *why*, as has been the burden of the spiritist and materialist of the past in the effort to comprehend the nature of things!

Conscious formative process produces, maintains and changes the forms of all the bodies provable to sentient perception, and therefore the bodies with which we become acquainted are products of, rather than producers of the metamorphoses through which we see them pass—progeny to antecedents and progenitors to sequence The occultness of which has been intensified rather than elucidated by the persistence of naturalists in insisting that bodies capable of being seen were produced by bodies like them without accounting for the origin of these progenitors

No end of work in mycological research has thus far resulted in nothing deeper than disputations respecting classification of blood, mucus, pus, proximate principles, pabulum and bacteria, without arriving at a reliable, clearly-proven starting point for function and factor of function without invading the almost untrodden fields of individual consciousness other than in a mass sense of ill-defined formulation of categories of being The limitations of ether, gas, liquid, colloid and solid forms of bodies are measured by degrees of combination, interpenetration and diffusion of energy, the press or urge of which sets up and maintains form, size and longevity or duration of all the bodies observed and observable by the naturalist, viz granule, corpuscle, tissue, organ and system as product of preordained measures of energy, upon the behest of which they all depend

Complete category of being, process and body, then, involves love and wisdom as the moving and directing energies of Infinite Consciousness, the Plenum of Light, filling immensity, the differentiated departments of which are displayed in circles, cycles, and systems of suns, planets and inhabitants of planets *ad infinitum*

The press, then, of the impact or epact of light + in ether awakens bonds of combining power of atoms in definite measure to form the granule, cell and corpuscle, and their aggregations subject to investigation and study by the psychist, physicist, naturalist and philosopher

Clear apprehension of the foregoing will teach the order of production of functioning bodies to be from the simple to the complex in formation and maintenance of individuals in mineral, vegetable and animal forms The stored energy remaining in each so long as it there finds greatest attraction for that particular measure of power which was awakened and engaged in the formation of the crystals, cells or corpuscles constituting the mineral, vegetable or animal bodies under observation

Opportunity for oxidation and hydration, then, is necessary to the formation of crystal—the water of crystallization being an essential element to maintain that form of body for so soon as this is driven out an amorphous powder of the metallic oxide is all that remains for examination

In the case of crystals of silex being deprived of their water of crystallization, opportunity is presented for the hydration of the amorphous silex, and we then have a jelly-like body known as "liquid glass," which upon dehydration returns to the solid crystalline state of silex Oxidation and hydration are the "digestion," "fermentation," "boiling" belonging to and occurring in the mineral kingdom Cellulation is the first act of digestion—fermentation—boiling in vegetable "protoplasm," and is capable of (amenable to) crystallization by dehydration, which is exemplified in a degree in the formation of ligneous fibre out of the cambium, which is protoplasmic When vegetable mass is deoxidized, alkaloidal residue holding high potency of stored radiance results, which may be poison, remedy or food to vegetable or animal feeders

Corpusculation is the first digestory, fermentative, cooking act in animal protoplasm

Nitrification is essential to form animal protoplasm out of vegetable protoplasm

When animal protoplasm is deoxidized leucomaines and ptomaines result upon the completion of the fermentative and putrefactive digestion producing these cadaveric chemical alkaloids

The investigation of these bodies is in its infancy, and we have much to learn before cataloguing all of them that are found, as really chemical individuals with provable identity But we are certainly nearing the point of illumination on this subject which will enable us to detect the antecedents of specific sicknesses more clearly than ever before Shall we not soon be able to antidote or abort all the exanthems resulting from infection by microbes?

I deemed it requisite to deal with histological physiology and retrogressive changes in protoplasmic bodies before detailing manipulations of using sterilized sponges, to fill the gap where tissues are lost, as a receptacle of the exudate to form the clot which is metamorphosed into protoplasm and embryonal corpuscles to form nerve plates, muscle-plates and bone-plates, out of which the new growth of tissue may arise in such exact imitation of the original parts as to defy detection as new growth by any macroscopic examination

The practice has now been followed long enough to confirm the hope and expectation first awakened when, some two years and more since, I was induced to attempt it The liability of failure will be lessened if the requisite conditions be well observed

1 A good state of blood crasis

2 Complete removal of dead or greatly debilitated tissue

3 Equable tension of the sponge graft

4 Complete coaptation of flaps of flesh over sponge graft, excluding all possibility of outward infection

5 Hygienic condition surely maintained First intention will then follow in flesh wounds and thoroughly disinfected old sores

Where it is impossible to secure good flaps large enough to cover in the sponge, I would not abandon the practice of using sponge as a means of filling out the part to normal size, but would let the sponge come fully to the surface and a little more, covering it in with sterilized gauze, over which only light bandages should be used

Two cases have proved failures in my hands, I *now* know because they were inserted before the parts were in proper condition Several partial failures of the sponge to "take" at certain places have made it necessary to clip out the part in which the new growth failed to appear, until the portion with copious "blood islands" afforded evidence of abundant supply by the blood freely following the removal of the sponge, which was without blood in it The "tacked" portion is then disinfected with either bichloride of mercury solution or, what I now prefer, potassio mercuric iodide one sixth as strong as the bichloride of mercury solution My habit is to use the pot merc iod solution (1 grain to 6 ounces of water, with about 1 ounce of alcohol in it to prevent formation of the red iodide of mercury during solution) two or three times a day as a spray, to insure aseptic state of the parts One further statement deemed important is disregard of extant doctrine about the necessity of removing all the blood corpuscles from the site of lesion where we desire to secure healing by first intention

The coagulable character of the whole column of good blood is to be conserved and courted, rather than removed and stanched, until no red corpuscles are in the tract of the wound

The best results I have ever seen have been in cases where coaptation of the lips directly over the sponge, without removing any of the oozing blood, was adopted, the great majority of which sealed up without any pus or other retrogressive form of the clot

My natural timidity, and faith in others almost to a fault, yet stands in the way of instant obedience to the clearer sight of immediate revelation of the *what* and the *how* of surgical procedure It is only that good may be done to like minded men, and through them to suffering humanity, that I earnestly counsel obedience to the revelation of truth in ourselves rather than to abjectly copy the lame instructions embodied in voluminous repetition of the effete doctrine of text-books

The whole system of drainage so strenuously insisted upon in text, and in hospitals, and in private practice, is a mistake, and a tacit confession that the dead and decaying part had not been thoroughly removed and the tract surely aseptic ized

---

STATISTICAL REPORT OF 5700 CASES OF EAR-DISEASES, CLASSIFIED BY AGE, SEX, OCCUPATION AND DISEASE, CAUSATION

Read in the Section on Otology of the Ninth International Medical Congress

BY S S BISHOP, M D
OF CHICAGO

The following statistical tables represent the records of 5,700 cases of diseases of the ear treated during the last eight years at the Illinois Charitable Eye and Ear Infirmary, in Chicago I have added a relatively small number of unselected cases from the records of my private practice to supply the place of those whose records were incomplete The purpose for which the classification was begun was to establish a basis of calculation of the influence, if any, exerted by occupation, age or sex in the causation of ear diseases The condition of each patient at the time he first presented himself at the clinic was recorded in order to determine the relative frequency of the different diseases

As is usual in charity hospitals, a very large percentage of those who applied for treatment belonged to that class of laboring people who have no definite trade or fixed occupation It is interesting, also, to note that the last decade embraced what might be called the vagrant era of the century in this country, for there never was a time in the history of America when such vast numbers of men were unemployed and leading nomadic lives This may partly account for the fact that about one third of the adult males are herein classed as being without occupation In order to facilitate investigation and simplify the tables as far as possible, all those occupations which were closely related to one another in nature and effects were grouped under one heading, so that the twenty-four which appear really represent about double that number For example, under the heading of clerks, were embraced salesmen, book keepers, office employés, etc , with teamsters were grouped car drivers, peddlers, etc , cooks and bakers were classed together, brass molders, iron molders, etc , were classified with iron workers, plumbers, gas- and steam-fitters appear together, such closely allied occupations as stone cutters, stone-masons, bricklayers and plasterers, in which the influences and exposures are very similar, are grouped together under the head of day laborers—a term borrowed from the laborers themselves

The abbreviations employed are
Ac for acute inflammation of the middle ear
Ac S for acute suppurative inflammation of the middle ear
C N for chronic non uppurative inflammation of the middle ear
C S , for chronic suppurative inflammation of the middle ear
Ext. for diseases of the external ear
Int for diseases of the internal ear
D M for deaf mutes
W No , for whole number

The tables show that more than one-half of all the occupations were in-door Of the 1590 males with fixed occupations, 920 worked out-of doors and 670 in-doors Add 1662 female adults who lead in door lives to the 670 adult males with in door work, and we have 2332 patients that spend most of their lives within doors To the 920 men who do out door labor we may add the 810 adult males who were without trades or any definite means of subsistence, and it gives 1730 men who probably pass most of their days in the open air Thus the excess of patients of the in-door class over those who lead out-door lives amounts to 602, or about 15 per cent of the whole number of adults These facts are significant when we take into account the slight difference between the number of males and females affected under the age of 15 years

Sex seems to have no influence in the production or prevention of these diseases It appears from this that up to the age of 15 years ear-diseases afflict both sexes nearly equally Possibly a reason for the slight difference which appears in the number of male and female cases during the first 15 years of life may be found in the similarity of the lives and habits of the sexes during this early period But the classes of society that afford clinical material at the medical charity institutions of this country are such that necessity requires them to abandon the pursuit of education at about the fifteenth year, and to enter upon bread earning vocations From that time the divergence in habits increases The males are either out-of doors more than ever, or confined chiefly to mercantile houses and factories The females become domestics, clerks and shop girls

American residences and business houses are heated in cold weather by dry hot air and kept at a temperature of 70° F , or higher The inmates are subjected to the action of this dry hot air, often laden with dust and noxious gases, the greater part of every day The skin, consequently, is very active in its functions, and kept moist by free perspiration But, though constant exposure renders the soldier, Spartan-like, indifferent to cold and storms, housing the body makes it tender, like the hot-house plant, and sensitive to sudden and extreme changes in the air After working all a winter day in a temperature of summer heat, these people, with the powers of resistance reduced by fatigue and hunger, pass out immediately into a frigid atmosphere, with the temperature perhaps from 40° to 70° F lower than that of the work shop The skin is chilled, the perspiration checked, and a determination of blood to some internal organ occurs Naso-pharyngeal catarrh is probably the most frequent consequence This result is aided by high winds and the inhalation of dust In fact a very large percentage of naso-pharyngeal catarrh is undoubtedly due to the irritating effects of dust, and this, operating in conjunction with cold damp air, is largely responsible for the wide-spread existence of naso pharyngeal catarrh among Americans It is undoubtedly the most prevalent disease in this country The importance of this fact is obvious when we consider that so large a number of middle-ear affections originate in naso-pharyngeal inflammation which extends from that cavity through the Eustachian tube to the tympanum. Critical examination of the throat demonstrates the existence of throat-trouble in a large proportion of these cases Hence, whatever causes a catarrh of the nose and throat is interesting to the otologist as a proximate cause of ear disease

The exanthemata are frequent causes of ear trouble during childhood, but youth seems to predispose to coryza which is often a forerunner of tubal and tympanic catarrh Children under 15 years of age constitute about 28 5 per cent , or more than one fourth of the whole number of cases Very many of them dated back to attacks of scarlet fever, measles and the earaches and "running ears" of infancy, so that a much larger percentage than appears should probably be credited to the period of childhood Only a small proportion of children were brought for treatment during the acute stage of inflammation Only 13 per cent were acute cases, leaving 87 per cent , or more than six times as many who had not applied for treatment until the inflammation had reached a chronic stage Indeed only 11 per cent of the adults were seen in the acute stage

The tables show a large percentage of diseases of the external ear Since impacted cerumen may be regarded as a symptom and a consequence of chronic non suppurative inflammation of the middle ear, due consideration should be given this fact in estimating the relative frequency of affections of the middle and of the external ear as shown in these tables

It may be permissible to cite a few facts that do not appear in the tables, but which, nevertheless, were impressed upon me by a personal study of this class of patients Although the whole State of Illinois contributed largely to the number embraced by these statistics, a large majority were residents of Chicago, a very cosmopolitan city The foreign element predominates The nationalities were not recorded except in resident infirmary cases, but the Irish constituted a very large, and the French a very small percentage of our clinical material The North of Europe furnishes a far greater percentage of our population than the Southern portions After considering the nationalities it will not be surprising when it is stated that the blondes exceed the brunettes in number

It was observed also that the nervous temperament was the prevailing one Another matter of interest to the etiologist, and to the student of sociology as well, was the conspicuous absence of baldness among these people, for cold draughts of air on heads

deprived of Nature's covering are considered as being a prolific cause of catarrh, by some authorities

This brings us to a consideration of the last topic of this paper climatic causes In speaking of climatic conditions as standing in a causative relation to ear diseases, it should be understood that reference is had to those atmospheric conditions which are characteristic of Chicago and its vicinity, although they may not be peculiar to it A sudden great fall of temperature, accompanied with increased humidity of the air, is usually followed by an increase in the number of new patients with acute diseases of the ear, and of chronic cases with acute symptoms These effects of atmospheric variations occur with such uniformity that we may predict an increase or decrease in the number of acute diseases with a reasonable degree of accuracy by observing the meteorological variations Our climate is rugged, but the people born and reared in it do not seem to partake of its robust character The altitude is low in the Mississippi Valley and the thermometric changes are sudden and great It is not unusual for the thermometer to fall 20° or 30° F , or more, in a few hours Indeed, cold-waves sweep suddenly over the country in summer time, cooling the heated atmosphere so quickly and so thoroughly that one must needs change from summer to winter clothing with haste or suffer from the chilling winds Add to these causes of great circulatory disturbances the irritating effects of constantly inhaled dust, which the ceaseless winds keep in never-ending motion, and the problem of the prevalence of naso pharyngeal, tubal and tympanic catarrh in our climate is in a great measure solved

THE TREATMENT OF HYPOPYON KERATITIS WITH FREQUENT IRRIGATIONS OF CORROSIVE SUBLIMATE

Read in Section on Ophthalmology and Otology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY F C HOTZ, M D ,
OF CHICAGO ILL

Progressive suppuration of the cornea is unquestionably an infectious disease and the destruction of the micro organisms is the surest means of arresting the progress of suppuration On this account the application of white heat (by electro cautery or otherwise) along the line of demarcation has proven so successful that it became a great favorite with ophthalmic surgeons But it is a treatment that cannot be trusted to any one but an expert, it destroys a certain amount of corneal tissue, thereby increasing the loss of substance, and the size of the resultant cicatrix, in the eyes of the laity it looks frightful and may easily create the impression that "the burning of the eye" has done all the mischief, if the case should take an unfavorable termination, and, lastly, the cauterization of the cornea does not affect the micro organisms which may have entered the anterior chamber, and therefore has no effect on the hypopyon and iritis

I therefore thought the question worthy of our consideration, whether we could not attain the destruction of the micro organisms just as promptly, and more thoroughly, by a simpler and less heroic treatment than cauterization, and during the past winter I made a series of experiments to answer this question In deciding upon the drug for my experiments I had to choose one that would be well tolerated by the eye, and passing through the cornea would be diffused in the aqueous humor in sufficient strength to exert its germicidal powers upon the contents and surroundings of the anterior chamber It seemed to me that corrosive sublimate would best fill these requirements A solution of 1 5,000 is not irritating to the eye, it certainly is taken up through the cornea into the anterior chamber, like solutions of atropine or eserine, and though it be greatly diluted by the aqueous humor it is known to be an efficient disinfectant and germicide in much weaker solution than 1 5,000 It was only necessary to keep the aqueous humor continuously charged with sublimate until all infectious germs were destroyed and until there was no possibility of further immigration of micro organisms from the corneal tissue

To accomplish this object the following plan was adopted The conjunctival surface of the lids and globe was thoroughly and repeatedly washed with the solution (1 5,000) until no trace of mucus was discovered in the fluid, then both eyes were bandaged with compresses wrung out of the solution, and the sublimate instilled into the affected eye every hour In dropping the solution into the eye the patient's head was well thrown back, the upper lid was lifted up with the finger and firmly held away from the eyeball for one minute at least, so that during this time the whole cornea was fairly inundated with the instilled solution

As soon as the appearance of the eye showed a decided improvement (and in every case this was manifested in 12 to 24 hours), the intervals between instillations were lengthened to two hours, and from that time on were gradually made longer in proportion to the better condition of the eye, when the hypopyon and the pus infiltration of the cornea had entirely disappeared the applications were reduced to three per day, and kept up until the cicatrization of the ulcer was complete

This treatment seems rather tedious, but when we take into consideration the fact that the frequent instillations are only required for 24 hours, and that any faithful person can attend to them, the treatment appears very simple, and in the 12 cases in which it was tested, it certainly proved very successful In every case, no matter how extensive the infiltration of the cornea and how large the hypopyon, the progress of suppuration was promptly arrested, in 24 hours there was a marked decrease in size of the hypopyon (or, if small, it had disappeared entirely), and of the characteristic cream-yellow infiltration of the edges of the corneal ulcer In no case was the cornea perforated if perforation had not occurred before the patient commenced treatment, and the resultant scars seemed less opaque than I have found them after other modes of treatment

All the cases were kept under observation until the defect in the cornea was completely repaired, the time of treatment varied, of course, according to the gravity of the case Several typical cases of ulcus serpens with small hypopyon recovered in one week, one similar case with pus filling one third of the anterioi chamber got well in 12 days, one other in 18 days, one eye with large central ulcer, with a streak of pus infiltration 4 mm wide, extending from the ulcer down to the lower margin of the cornea, recovered in 3 weeks with only a small haziness in the centre of the cornea Even in the severest cases the time did not extend beyond one month

In one case the treatment was put to a very severe test A little boy 3 years old was brought to me on the 18th of February For three weeks his left eye had been inflamed, and from the first his mother had noticed a yellow spot in the cornea Her physician, making light of the trouble, told her the eye would be well in a few days, but it grew visibly worse from day to day The child was manifestly in great pain, his lips were parched, his tongue dry, his breath very offensive The upper eyelid was swollen enormously, so that it was very difficult to open the eye far enough to examine the cornea The ocular conjunctiva was very red and œdematous, cornea smoky, and in its temporal half a pus infiltrate 7 mm long and 4 mm wide, its irregular borders considerably raised over the level of the surrounding surface In the deeper layers of the cornea the pus extended even far beyond the surface margin of the infiltrate, hypopyon of 4 mm In this case I used the solution 1 2,000 The next day the hypopyon was smaller and the suppuration of the cornea had not advanced On the second day it was decidedly less, on the third day the œdema of the upper lid and the chromosis of the ocular conjunctiva had subsided, and the last trace of hypopyon disappeared By the fourth day the whole area of the corneal abscess was transformed into a simple ulcer with gray margins, and on the 4th of March this ulcer was healed, the gray opacity measuring 4 by 2 mm , the pupil regular and free This case was not in a hospital under the care of a trained nurse, but the treatment was entrusted to the boy's mother, whom I showed the proper way of applying the solution, and who fully understood how much depended upon her following my instructions to the letter

CANCER OF THE RECTUM

Read before the Louisville Medical Society,

BY JOS M MATHEWS, M D ,

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL LECTURER ON DISEASES OF THE RECTUM, KENTUCKY SCHOOL OF MEDICINE VISITING SURGEON TO LOUISVILLE CITY HOSPITAL AND STS MARY AND ELIZABETH HOSPITAL LOUISVILLE ETC

That was a quaint description of cancer given by Lorenz Heister, in 1731, in which he says "When a scirrhus is not reabsorbed, cannot be arrested, or is not removed by time, it either, spontaneously or from maltreatment, becomes malignant, that is, painful and inflamed, and then we begin to call it cancer " We are amused at this homely definition by the old master, but when we stop long enough to think, we can honestly ask ourselves, "How much beyond this have we advanced in the study of this much dreaded disease?" Even with our much vaunted knowledge of anatomy, histology and pathology, the most learned of us call a halt before pronouncing upon the character of tumors, drawing the line, as it were, between benign and malignant growths The daily press heralds one day that the Crown Prince has a warty excrescence in his throat, the next cablegram is that it is a deadly cancer The great surgeons disagree, and it is agreed to send a *specimen* to the learned Virchow, and have the *microscope* settle the disputed question An American doctor on the Western plains might ask, "What is the use of all this? Can't they tell by looking at and feeling the growth?" In other words, are not the physical signs and clinical history of much more value in determining the nature of suspected tumors, than anything that the microscope can reveal? That the *cells* have proved inefficacious, the *alveolar* formation not a certainty, and *epithelial proliferation* not a guarantee, is admitted, or at least mooted So it may be, as Billroth says, "In a hundred years will they laugh at our present anatomical and clinical definitions of cancer " There are two questions that force themselves upon our attention at once, when dealing with suspicious growths 1 Is it a malignant or non-malignant tumor? 2 Is its removal advisable? To tell a person who comes to you for honest advice, that they suffer from cancer, when there is a doubt, is little less than criminal, and yet there are circumstances that might demand a positive opinion, if such was held I am not in the habit of telling my patients of the existence of cancer By so doing I am satisfied that life is shortened Thus we see that a diagnosis becomes of the greatest moment How are we to arrive at a correct conclusion?

Diagnosis —It is not the purpose of this paper to deal with the histological aspects of cancer In making a diagnosis of the disease I seldom rely on the microscope In my opinion the clinical features are of the most importance My remarks apply equally to cancer wherever located, deeming the characteristics of the disease the same without regard to locality Without stopping to argue, I will state a few observations that I believe to be facts I am firmly convinced that cancer is a local disease, due to traumatism and irritation, and that heredity plays no part in it I have long since ceased to question for family history If it should exist I would take it only as a coincidence More escape cancer, in my opinion, where family history of the disease exists, than have it under the same circumstances The so called *cachexia* of cancer is misleading In advanced stages of the disease I have sometimes anticipated, but not recognized it The same appearance may be seen under many conditions The same pallor, emaciation, etc , arise from other diseases I do not believe in any *facial* indication of cancer If it exist, it is due to *fear* rather than infection The man under sentence of death

is likely to have it Neither do I believe with Mr Allingham and others that the *odor* of cancer is pathognomonic I am sure that in many cases it is absent The authors are accustomed to give *hæmorrhage*, or a disposition to bleed, as one of the symptoms of cancer It is not at all characteristic I have now under my observation five cases of cancer, none of them have ever lost enough blood to call it a factor in the disease *Pain* is pronounced a prominent symptom, even its *character* is said to be peculiar My record book will show a number of cases that have died with the disease, and pain never existed to any degree *Age* is said to play its part as well Indeed, I have heard some physicians exclude the thought of cancer because "the patient was too young " In my experience I have met with two cases of cancer in patients under twenty years of age, and one under seventeen The majority of such cases observed by me have been under the age of forty five *Touch* is said to indicate much in determining the diagnosis I have often felt for that *gritty* feel, and not found it Hence I am inclined to believe that one or more of the so called symptoms of cancer may be absent If, then, the microscope is not infallible, and many of the physical signs absent, how are we to determine the question? I shall only speak of making a diagnosis when the disease is located in the rectum, and deal with the distinction between malignancy and non malignancy, not caring to enter into a discussion of the different classifications of cancer I recognize the fact that certain conditions are malignant which are not cancerous, yet I deem it quite sufficient for the purpose of elucidation, to speak here only of these two types To attempt anything further than this would bring us into the consideration of many knotty questions We have attempted to show that it is a difficult thing to be certain in a diagnosis of cancer, and I am equally sure that the uncertainty is just as great when we attempt to designate the time that a benign tumor has become malignant After a learned dissertation upon the histological aspects and microscopical evidences of cancer, Billroth says "I acknowledge that it is difficult to distinguish carcinoma from adeno sarcoma and alveolar sarcoma " Therefore, to sum up in the matter of making a diagnosis, I would say that the symptoms to be relied on most are (*a*) The disposition to ulcerate, (*b*) rapid infiltration, (*c*) secondary deposits Certainly these are more trustworthy than many of the so called symptoms, or the revelations of the microscope *No surgeon should be guilty of making a positive diagnosis of cancer, with or without the microscope, until he has learned the clinical facts of the case*

Method of Diagnosing Cancer of the Rectum — Nothing should be taken for granted in examining a patient for rectal disease I have known cancer of the rectum treated for piles, and *vice versa* A history of the disease, with symptoms, should be related by the patient, and not by a second party If cancer be present, some or all of the following symptoms will be mentioned Pain in the back and thighs, lassitude, morning diarrhœa, flatulency, straining at stool, the passage of some blood, mucus, or pus All these may arise from simple ulceration of the gut, but they are, to say the least, suspicious An examination of the rectum should now be made The best position for the patient is upon the left side An inspection of the external parts may reveal much or nothing It is generally stated that cancer frequently begins at the anus, especially the epithelial variety This is not my experience, out of an observation of at least one hundred cases the fewest have had their origin at this site Should this be the part attacked, an external observation, of course, will reveal the fact, if not, then but little evidence will be shown on the outside of the rectum I have had many cases come to me for examination for some supposed trivial rectal trouble, and it revealed the rectum filled with a cancerous growth After a thorough inspection of the external parts, the rectum proper should be examined This should never be neglected I have known patients to be operated on for fistula in ano, the surgeon neglecting to examine the rectum, where a cancer existed Upon more than one occasion I have seen patients who had their *piles* (?) operated on by tying, or injecting a portion of the cancerous mass The best method of examining the rectum is with the finger It should supersede all instruments I have long since discarded the speculum save in the fewest of cases There are but two conditions, to my mind, with which cancer in the rectum could be confounded 1 Simple ulceration with inflammatory deposit 2 Sympathetic ulceration, with consequent stricture Mistakes have often been made I have made them *First* From simple ulceration with inflammatory deposit Simple ulcerations can usually be traced to some definite cause, as dysentery, foreign bodies, etc To the touch the induration has a smooth, continuous feel The ulceration is more or less clear cut, and the discharge is like that from the same kind of ulceration elsewhere If epithelial cancer, a firm growth will be felt involving only the mucous membrane at first, and freely movable If scirrhus, *hard* nodules are found around, and involving, the prostate gland If cancer proper, secondary deposits occur in lumbar glands, groin, liver, etc If simple ulceration, there is no disposition to infiltrate, or of the growth to break down If cancer, the tissue yields to pressure, and infiltration takes place rapidly Hæmorrhage from either condition is hardly a factor, as neither, in my experience, bleed much, except in rare instances, as for instance the uncovering of an artery by degeneration of its coats in cancer The odor, as I have said, is not pathognomonic Some confusion might arise over gland involvement It is true that simple inflammatory action in the rectum may excite the same condition in the adjoining glands, as in the axilla, from mammary irritation, or in the groin, from rectal inflammation The question would naturally arise, "Is an inflamed gland already infected?" I could scarcely admit this as a principle, and yet no one can definitely say just when lymphatic infection takes place

Second From syphilitic deposit with consequent stricture —Whenever ulceration is found in the rectum

it is well to suspect syphilis as a cause I make this rule apply to all stations in life The rich and the virtuous may be the victims as well as the poor and degraded In an article read before the Kentucky State Medical Society several years ago I maintained that syphilis was the *most* frequent cause of stricture of the rectum, and not cancer as stated by some I am equally sure that many cases of syphilitic ulceration of the rectum are mistaken for cancer Anticipating syphilis then in all these cases the history should be traced, and the throat, skin, scalp, shins, etc , carefully examined

Case —Dr B asked me to see a young married woman, with him, who was suffering from a stricture of the rectum The doctor was inclined to believe that the condition was caused by pregnancy, the patient having borne a child about a year before Upon examination a stricture was found, beginning one inch above the sphincter muscle It was impossible to introduce the smallest finger through it A free division was made through the constricted surfaces After this her general health improved and she took on flesh During one of her visits to my office she remarked that she had failed to call my attention to an eruption that had been on her body for some time I looked at it and suspicioned syphilis but referred her to a dermatologist who pronounced it some skin trouble and prescribed an ointment She used this for a long time without effect I then put her on fifteen gr doses of iodide potassi, and at the end of three weeks the eruption had disappeared Arguing from cause and effect I concluded that this woman had syphilis and that this disease was the cause of her stricture—I am certain that the woman was virtuous There is a wide difference to the feel between cancer of the rectum and syphilitic stricture The induration from syphilis is firm but not nodular and does not yield to pressure There is no rapid infiltration of tissue and contiguous parts are scarcely invaded The discharge from syphilitic ulceration is more like that from simple ulceration, and not like the degenerated tissue discharge of cancer The strictures from syphilis are like fibrous bands, while from cancer they are nodular bands which degenerate Hence I imagine that the diagnosis between syphilitic ulceration of the rectum and cancer can be easily made

Treatment —The treatment of cancer of the rectum involves more serious questions than when dealing with cancer of the breast, lip, tongue, and many other favorite sites of the disease Ordinarily, the question of removal of the growth is the first to present In cancer of the rectum it must needs be the last considered It is quite an easy thing to remove the mammary gland, or excise an epitheloma from the lip It is a much more serious thing to remove the rectum Those who advocate the removal of cancer do so for the following reasons

1 It may effect a cure
2 If not, it prolongs life
3 It removes from the sight the offending mass
4 It lessens, or eradicates pain
5 For physiological effect

As I shall take exception to some of these, you will permit me to deal with them separately 1 It may effect a cure That some forms of malignancy have been cured by operation cannot be denied I have known cures to result from the extirpation of epitheliomas, say of the lip, eye lids, etc It has been my fortune to witness many removals of the mammary gland for cancer, it has been my misfortune to know that each time the disease returned Of course other surgeons can report better success than this I have often wondered if the bad success in this particular operation was not due to the method of operating With all due deference to my antiseptic friends, I am not yet convinced but that the plan of Volkman, to remove the whole breast and allow it to heal by *granulation*, is the proper one We often wonder if some of the cancer cells have not been left within the *flaps* Pus here would not be so dreadful an enemy as it is often made out to be Surgeons will often extirpate the breast, and leave untouched the axilla, filled with infected glands, or perform hysterectomy with all the adjoining lymphatics embraced in the disease We have all seen patients submitted to an operation when a clearly defined cachexia existed All this leads me to say that I believe that the operation for cancer is done much too often, many times when there is no earthly chance of doing any good This is wrong, and subjects the profession to criticism May I not say to *just* criticism In collecting data for the successful operations for cancer, statistics are very unreliable As this paper has indicated, perhaps, the disease was not cancer, or the time elapsed was not sufficient to base an opinion on According to the observations of Paget, Sibley, Billroth, Allingham and others, the duration of life in patients with cancer, from the first manifestation of symptoms, is three to four years No one can say how long the disease actually exists before the symptoms are made manifest Suppose then that a surgeon collecting statistics for his successes in these cases affirms a cure before the expiration of this time, or that he had even prolonged life It could be replied that patients had lived as long *without* an operation Some time ago I made a report of two successful operations for cancer of the rectum Since that time one of the patients has died with the disease, although he lived several years after the operation Billroth reports thirty-three cases of the removal of cancer Thirteen died of the operation, aud the remainder all died within two years, most of them of recurrence With such results from such an authority, ought we not to think seriously before doing the operation?

Second —The operation may prolong life To my mind this is an unproven claim I believe rather that surgical interference often hastens a fatal result I know that the great majority hold a different view, but when the disease has become constitutional, the blood corpuscles already changed by the action of the juice, or cancer cell, it is hard to believe that the removal of the growth will stay the disease When lymphatic infection has once taken place, we have yet to discover that power which will prevent its steady march Patients die of the constitutional, not the local effects of cancer

Third —It removes from sight the offending mass This can only apply to growths on the external surface of the body I must confess that the reason carries much weight with it, but would the patient not be a great convert to asthetıcism to ask an operation for this cause only? It would be like painting Camille's cheeks with rouge during her death struggle

Fourth —It lessens or eradicates pain In answer to this I would say that the truth of this depended much upon circumstances If the cancer be located in a part where there was great nerve involvement, it would be likely to involve more than could be removed, and we know that a partial operation would accomplish but little If a cancer absolutely interferes with the use of an organ, say the eye, tongue, etc , I would much prefer to remove the growth because it did so, than because of the pain it excited

Fifth —For physiological effect I must say that I see more plausibility in this reason than in reason third If the patient is convinced that by operation something has been done looking to a cure, then there is surcease of sorrow, at least for a season Yet I do not believe from a surgical standpoint, that the operation should be done either for the third or fifth reason alone

Methods of Operating —There are two plans suggested in a surgical way, for the relief of cancer of the rectum, viz extirpation and colotomy In a word I would say that if an operation for the removal of cancer is decided upon, then a *sweeping* operation should be done I would never remove a *segment* of the rectum If an operation is called for at all it requires the removal of the rectum in its entirety From my own experience and that of others, backed by pathological reasons, I am constrained to say that I do not believe extirpation is warranted in cancer of the rectum My reasons for opposing *colotomy* as a means of relief in many of these cases, were recited in a paper read before the International Congress, and will appear in the published proceedings of that body

FORENSIC RELATIONS OF THE PUERPERAL MENTAL STATE

Read in the Section on Medical Jurisprudence, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887,

BY HARRIET C B ALEXANDER, A B , M D ,

OF CHICAGO ILL

FORMERLY ASSISTANT PHYSICIAN COOK COUNTY INSANE HOSPITAL

The mental state of the puerperal female has not received the attention its forensic importance merits from lawyers and physicians, owing to the erroneous lay opinion, shared by many members of the medical and legal professions, that pregnancy is now, what it once was in the history of the race, a normal physiological process

Pregnancy, if regarded in this light, stands alone, since no other physiological function presents the pathological phenomena pulmonary, cardiac, gastric, renal, cystic, nervous and other disturbances characteristic of pregnancy Even "labor," that terminates pregnancy, is characterized by the pathological phenomenon "pain" It is illogical to speak of a condition in which *pain* is present as a physiological state Pregnancy unattended by pathological phenomena is the rare exception, so rare that it may well be doubted whether these cases are properly observed, since too little attention is paid to nervous and mental phenomena that do not reach the dignity of paralysis, spasms, contractions, amaurosis, amblyopia, odontalgia, hallucinations, delusions maniacal outbursts or furor That pregnancy at one time was a purely physiological process may be admitted, that it now is no one but a *doctrinaire* will claim after careful examination of the subject

Many causes have contributed to transform this originally physiological state into a pathological one Dr Clevenger most ingeniously points out, for example, that "if we are to believe that for our original sin the pangs of labor at term were increased, and also believe in the disproportionate contraction of pelvic space being an efficient cause of the same difficulties of parturition, the logical inference is inevitable that man's original sin consisted in his getting on his hind legs" To this original sin of assuming the erect position have been added the effect of atrocious modes of clothing, feeding, housing, employing and training one part of the race, which have checked their pelvic development while other forces have augmented the cephalic development From almost the beginning of the race forces have been at work which have decreased woman's usefulness purely as a woman, and made her, man's embryological superior, his actual inferior in the struggle for existence

The Teutonic races, in which woman held a high place, have too often accepted the Latin doctrine, that there was nothing more than woman's caprice in the mental state of the pregnant woman, and have held her strictly responsible for the results of what their public opinion held to be a pathological state As Ben Jonson's plays show, Anglo Saxon popular opinion regarded the pregnant woman as irresponsible for her "longins'," a most natural and just view, since on careful analysis of the mental condition of the pregnant woman it is apparent that this is always affected by more or less morbid perturbations of the (monarchical) cerebral vaso motor centre, secondary *first*, to pelvic fluxionary changes, *second*, to irritative conditions, *third*, to conditions of exhaustion, *fourth*, to pressure neurosis of cardiac, pulmonary, gastric, visceral or peripheral neuric origin These factors of disturbance are always present in the puerperal state I include the period from conception to the termination of early lactation

The circulatory condition of pregnancy, as Cazeaux and others point out, is essentially that of chlorosis, which has been shown to be a trophoneurosis by Dr Hammond The irritative conditions result from the general nervous and circulatory disturbance of which this circulatory neurosis is the expression, and are secondary to local and general inflammatory states, tears, erosions, displacements, etc The conditions of exhaustion originate from the conditions last described, and are often secondary to severe or prolonged labor, lactation, too frequent pregnancies,

poverty and, in the abandoned and seduced, to the nervous agitation resulting from the surroundings

The mental changes consequent in fluxionary pelvic changes are emotional morbidity, depression, abulia varying from simple apathy to extreme loss of will power, or destruction of the logical inhibitions render the pregnant woman subject to undue influence, to morbid suggestions and to pure imperative conceptions Emotional morbidity leads to infanti cide through accidental neglect Apathetic abulia has the same consequence, since it weakens the natural affections Abulia readily leads to infanticide through a paramour's suggestion, by the perusal of child-murder cases, morbid suggestions, cannibalistic sexual furor and pure imperative conceptions Depression, a potent cause of infanticide in non-parturients, much more often leads to it in the pregnant, whose will and natural affections are blunted still more by the puerperal state The mental conditions resulting from the causes mentioned are, as every obstetrician and pregnant woman will admit, peculiarly destructive of the free determination of the will

In all Teutonic countries where popular prejudice has not intervened it is still held that there is no criminal act where the actor at the time of the offense is in a state of unconsciousness or morbid disturbance of the mind that prevents free determination of the will According to this rule the admitted mental consequences of febrile fluxionary changes are amply sufficient to *compel* the State to demonstrate beyond *doubt* that free determination of the will of the pregnant or just delivered woman has not been *impaired* These pelvic fluxionary changes are, as has already been pointed out, not the only influence at work Abulia the result of disturbance of the emotional balance, one of the most common and distressing of mental states, is produced by any or all the conditions mentioned It may vary from slight weakening of the logical inhibitions to states where they are in complete abeyance Women otherwise seemingly healthy complain of this lack of will power or "energy," and find great difficulty in controlling themselves In all conditions in which the will or logical inhibitions are impaired imperative conceptions arise, sometimes of pure type, sometimes suggested by morbid sensations From these conditions also results that capriciousness which characterizes the puerperal state Besides this caprice, emotional morbidity and abulia produced by all the pathological factors mentioned, the local effects of these factors peculiarly modify the mental state

Pressure on the heart, lungs and stomach engenders suspicional mental states, which create delusions of persecution accompanied by ideas of poisoning and impaired appetite (of pulmonary, cardiac, or gastric origin), or of strangling and poisoning (of cardiac and pulmonary origin) Pressure on the peripheral and visceral nerves sets up various types of hyperæsthesia which persist long after the original pressure is removed, and tinge the mental state It hence creates erotic and suspicional mental states Any physician of extensive practice will remember cases varying from slight eroticism just beyond the patient's control to the openly expressed eroticism of puerperal insanity The various "longings" of the pregnant woman arise from imperative conceptions either pure or dependent on perverted sensations, or from reversions to early habits of the race during reproduction So long as these longings were of trifling character their morbid nature would not be disputed, nor considered worthy of thought, but let a pregnant woman kill and eat her husband, or a newly delivered woman, in that peculiar frenzy for blood that arises from perturbed sexual states, kill her child, and these ludicrous longings furnish a psychological key to such actions of great forensic importance Every woman during the pregnant state is, it will be obvious, subject to influences that weaken her will, engender emotional morbidity, render apathetic natural affection, and give rise to ideas of suspicion as well as to perverted sensations and propensities

Legally these mental states predispose to murder, infanticide, nymphomania, arson, sanguinary cruelty, dipsomania and kleptomania, either pure or resulting from a desire for possession dominating a weak will The literature is full of illustrative instances When a well-to do puerperal woman steals the public authorities willingly admit the plea of kleptomania, but when the poor hunted, seduced woman steals she is too often treated as a criminal If a married woman kill her newborn child no jury will convict her Let a seduced and abandoned girl do the same and a public example is demanded (*pour encourager les autres*) Yet in this last case the power of self-control is much more weakened, not only from the puerperal state but from other moral effects engendered by seduction, desertion and dread of exposure This is arrant injustice, that can only be defended on the tyrant's plea of necessity for the protection of society, a plea, as history shows, based on ignorant prejudice Severe penalties never decreased infanticide, since the seduced infanticide never could appreciate the bearing of these penalties This was well illustrated by Goethe, who never drew a truer or more pathetic picture than that of Margaret about to be executed for an infanticide springing from the perturbed mental state clearly evident in her last interview with Faust

In conditions of doubt justice leans to the presumption of innocence From what has already been said it must be evident that the mental state of the puerperal woman is a dubious one In Illinois, it would be sufficient to make the claim that the mental condition of the puerperal woman was unsound, and the burden of proof would immediately fall on the State, in obedience to the old legal presumption of innocence in every man In Indiana and New Hampshire the same just doctrine is held Mental states are matters of fact, not ideal creations of law It is sad to say that in the majority of our States the burden of proof falls on the prisoner in all cases in which insanity is a defense, and what insanity is, is determined by legal tests set up decades ago under pressure from English precedents Barbarous as these legal doctrines are, they are held in

Alabama,	California,
Delaware,	Kansas,

Maine,	Georgia,
Massachusetts,	Michigan,
Missouri,	Mississippi,
Minnesota,	Nebraska,
New York,	New Jersey,
Ohio,	North Carolina,
Pennsylvania,	Tennessee,
Texas,	Kentucky,

Federal Courts

These cruel absurdities have their natural result Judges, unable to rid themselves of legal superstitions, resort to subterfuges to avoid enforcing the alleged law in cases in which crime was the offspring of insanity not covered by the legal definitions In the infanticide case of "The People vs Kate Harvey" expert testimony was not introduced until after the jury had convicted the prisoner, but the judge allowed the mental condition produced by the puerperal state to mitigate the sentence The absurdity of such procedures is well summed up by Judge Doe, of New Hampshire "If tests of insanity are matters of law, the practice of allowing experts to testify what they are should be discontinued If they are matters of fact the judge should not longer testify without being sworn as a witness and showing himself qualified to testify as an expert"

In dealing with any forensic question the physician's first duty is to determine whether such a thing is a fact, not whether it might under certain supposable conditions have a bad effect on society Once ascertained to be a fact, it is his duty to declare it such In this spirit I have striven to prove that in crimes committed during the puerperal state the burden of proof lies on the State, since the alleged criminal suffers from a pathological state predisposing to violations of major and minor morality The law, in its assumption that every one is innocent, regards crime as an unusual state, and this presumption of innocence is strengthened if the state of the alleged criminal predisposes to unwilling violations of morality

SUBPERIOSTEAL RESECTION OF A RIB FOR EMPYEMA IN CHILDREN, RECOVERY

Read before the Chicago Medical Society, October 17, 1887

BY ALBERT B STRONG, M D,
OF CHICAGO ILL

I have within the past two years made subperiosteal resection of a segment of a rib for empyema in two young persons, one a boy of 6 and the other a youth of 17 years of age The results have been so satisfactory that I desire to place the cases on record at the present time, particularly so, since able authority has recently condemned the operation in children[1]

Case 1 —In May, 1886, I saw in consultation with Dr Charles Venn, of this city, a boy 6 years of age The father, mother and other children of the family were perfect pictures of health The boy was large for his age, and up to his present illness had always enjoyed the best of health Four weeks prior he began to cough, and eight or nine days later evidences of an effusion into the right pleural cavity were manifest In spite of appropriate constitutional and local treatment, the effusion increased, and when I saw him the chest cavity was completely filled The boy was much emaciated with continued fever and night sweats

A hypodermic needle thrust into the chest just above the eighth rib in the axillary line, revealed the presence of pus Under ether the eighth rib was exposed through a parallel incision two inches in length The periosteum, midway between the upper and lower border of the rib, was split in a longitudinal direction, the distance of an inch By means of a blunt hook the periosteum and intercostal vessels were easily peeled off from the posterior surface of the rib, and three fourths of an inch was cut away with bone nippers This was done without wounding the intercostal vessels or pleura Next the internal layer of the periosteum was split to the same extent, and parallel to the external layer The pleura was opened when two quarts of laudable pus were evacuated The chest cavity was immediately washed out with a warm saturated solution of boracic acid, and a large rubber drainage tube retained in position

The subsequent history was uneventful He began to improve at once The chest cavity was daily washed out with simple warm water A wad of oakum was placed over the wound The tube was kept in place six weeks, when the lung was entirely expanded and the wound healed completely Now, sixteen months after the operation, the boy is perfectly well The right chest is normal like its fellow, in shape and function There is but a small scar at the seat of operation, and the rib has perfectly reformed in direction and shape

Case 2 —Norwegian boy, 17 years of age, always delicate, very thin and poorly nourished, six feet tall, pale and anemic Father, brother and one sister, died of consumption Mother alive and doing well Patient was first taken sick about March 10, 1887 The symptoms and signs indicated pleural pneumonia of the lower lobe of the right lung In a few days he was convalescent

On March 24, he had a relapse, and the right chest slowly and intermittingly filled with effusion He had night sweats, diarrhœa and cough, and a temperature of 102° to 104° F On April 24, about five weeks from the commencement of the effusion, empyema being diagnosed by the hypodermic syringe, with the assistance of Dr Venn, I removed subperiosteal, one and one-half inches of the 9th rib in the axillary line Four quarts of laudable pus escaped At the last about four ounces of clear serum passed out Immediately washed out the chest cavity with a hot solution of boracic acid, introduced two large parallel rubber tubes with a drainage diameter of three eighths of an inch each These were held in position by a rubber shield and elastic bandage around the chest The pleura was felt to be about three-fourths of an inch thick Dur-

[1] See an article by Dr Garnett of Washington on The Surgical Treatment of Suppurative Pleurisy in Children published in THE JOURNAL, Sept. 17 1887

ing the next few days there were washed out large masses of lymph Hot water injections of two quarts at a time were used, night and morning A wad of oakum was kept over the opening and changed often The diarrhœa, sweating and cough began immediately to abate The temperature in three days dropped to normal On the first day of May, eight days after the operation, the tubes were crowded out All the unfavorable symptoms had disappeared, he was eating and sleeping well The opening on the inside was closed, as I then thought by the expansion of the lungs, I subsequently learned it was closed by the arching of the diaphragm The tube was left out five days, when the temperature began to ascend, and soon reached 104 There was a return of the sweating, diarrhœa and cough Nothing had escaped from the wound in the meantime I then reopened the wound and washed out about five ounces of stinking pus and débris, passed a large Van Buren urethral sound into the chest, and ascertained that the lung was compressed into a small wad against the vertebral column It had not expanded a particle I felt the apex of the sound in the chest above the clavicle Reintroduced longer, fenestrated drainage tubes, three inches in length From this time on his convalescence was uninterrupted Temperature quickly became normal and did not again rise He soon began to go out of doors and improved rapidly On June 12, three weeks after the tubes were reintroduced, my notes read Boy has gained ten pounds, out of doors most all day Eats enormously and digests it well No cough and but little discharge The sound in the chest shows the lung has not expanded Put in drainage tubes without fenestra, since granulations had crowded into the former tubes so as to nearly occlude them Sent the boy to a farm near Whitewater, Wisconsin, with instructions to keep tubes in position, and syringe out the cavity once a day with warm water that had been boiled Ten weeks later, on August 25, he returned looking altogether different Was twenty pounds heavier than when first taken sick, and expressed himself as never feeling better in his life The tubes had remained in place until a few days before, when they had been crowded out and could not be reintroduced Physical examination showed the lung expanded with good motion of the chest and vesicular murmur throughout In a few days more the opening entirely healed and the boy left for Norway, perfectly recovered, six months from the commencement of his illness and four months wearing the tube

It is only within a few years that surgeons have been bold enough to make a section of a rib for empyema It is, perhaps, but natural that the operation should be condemned by those who have always used the trocar or incision To oppose the operation on purely theoretical grounds and conclude that it is a grave and serious operation, is, I believe, contrary to the facts in the published cases

In the article alluded to in the commencement of the paper, we find a table by a London writer of thirty-four cases of empyema, treated surgically, occurring in children of from 1 to 10 years of age Of the number seventeen recovered after a short section of one rib had been made The average time of recovery was seven weeks

Dr Garnett reasons that had these cases been treated with the trocar and drainage tube they would in all probability have recovered equally as well Here is what he says against exsection "When we consider the fact that the bony fabric of the chest is still in a condition of progressive development, the rapid and excessive deposit of callus following the solution of continuity of a rib protruding into the cavity of the chest, irritating the lung, the inevitable disparity and loss of symmetry in expansion of the two sides of the thorax, the growing condition of the child, which necessarily adapts itself to the physical results of the traumatic interference, establishing often a permanent deformity, associated at times with more or less spondylitis, and greatly restricted respiratory capacity of the chest, the pouch of periosteum from which the excised piece of rib has been dissected, the protracted healing and long-continued dressing of the open wound augmenting the chances of septicæmia, and exhausting the vital energies and recuperative resources of the little sufferer We should hesitate before resorting to so grave a surgical procedure when a more simple and conservative one can be safely and successfully practiced "

Such conclusions, I think, should not go unchallenged One does not find them from a careful study of these cases The simple questions that I should like to invite your discussion upon is Is subperiosteal cutting away a short segment of one rib with modern surgical treatment, liable to be followed by such grave consequences as the writer referred to would have us to believe? Free drainage in abscess cavities is the imperative rule at the present day This is best obtained by making a patulous opening larger than is possible to make between the ribs In my first case the rib has completely reformed In the second it is growing again In neither case did callus injure the lung In both cases lung expansion and chest motion and shape are perfect Septicæmia present in both cases, was quickly cut short by free irrigation, only possible through a large opening

I would therefore conclude that in these two cases, section of the rib at least added nothing to the gravity of either case

MEDICAL PROGRESS.

PRESYSTOLIC HEART MURMURS —At the meeting of the Medical Society of London, on November 7, DR J S BRISTOWE read a paper on this subject He divided mitral obstruction murmurs into three varieties, namely 1, one beginning from the second sound and ceasing in the course of the diastolic period, 2, one occurring isolated in the diastolic period, and 3, the murmur (to which the names presystolic and auricular systolic are indifferently applied) lying along the diastole and running up to the

first sound He likened the sound of the last of these (which is usually louder and rougher than the others) to that of the trilled R, and the sound of the two to that of an untrilled R, but observed that, although they sufficiently often occurred, separately to merit individual description, they not infrequently coalesced, in which case the whole of the interval between the second and the first sounds was occupied by a more or less continuous roar, the earlier portions of the sound often then becoming as loud and rough as the later part Although he admitted that the presystolic portion was usually louder, owing to the fact that it occurred while the auricle was contracting on its contents, and propelling them forcibly into the ventricle, he held that the rate of blood flow from the auricle into the ventricle, even when the auricle was quiescent, was amply sufficient to cause the coarse vibrations giving rise to a trill, and he argued that that was the main reason why these murmurs were heard over so small an area, and that the sound was consonantal in character and not musical He discussed the questions of the relative feebleness of the second sound due to the aortic valves, of the frequent reduplication of the second sound, and of the cause of the apex thrill, and expressed concurrence in the views generally taught He argued that the presystolic murmur could not be a systolic murmur, as Dr Barclay, Dr Dickinson and others maintained, because 1 The assumption that there is a noiseless period of ventricular contraction prior to the closure of the mitral valve is not in accordance with physiological facts 2 If the murmur occurred during the early systole, it ought to be coincident with the apex beat and the pulse, whereas it preceded them 3 If this explanation of the presystolic murmur be correct, there ought also to be at the same time a presystolic aortic murmur And, lastly, the presystolic murmurs are of the same quality as the earlier murmurs, which were undoubtedly diastolic, and are but carried back into the auricle as a regurgitant murmur necessarily must be In the last place he drew attention to hæmic murmurs existing in the pulmonic area, and showed that they so far resembled obstructive mitral murmurs that they were rough, and that they tended to occupy the whole period of systole and to run up to the second sound —Dr Dickinson, in paying a tribute to the ability of the author of the paper, expressed his regret at having to join issue with him on the subject of these murmurs He alluded to the means of differentiating an aortic regurgitant from a diastolic murmur by change of position —Dr Sansom went very fully into his reasons for differing from the previous speaker, and rallying to the ideas of Dr Bristowe and Professor Gairdner, he maintained that the snap which terminated the presystolic murmur was not due to closure of the mitral valves, but suggested that it was due to the tricuspids —Dr Burney Yeo said he had at one time collected a large number of heart cases, sixty in all, in six of which a well defined presystolic murmur was present He mentioned that in describing the character and relations of this murmur it was necessary to describe the action of the heart at the time of observation, whether fast or slow —Dr Broadbent said he endorsed every word of Dr Bristowe's paper He urged that Dr Dickinson's assertions that the snap terminated the ventricular systole and concluded the diastolic murmur were irreconcilable He thought Dr Sansom's idea of the cause of the snap was probably not the correct one —Dr Ord contented himself with approving the ideas expressed by the preceding speaker —Sir Dyce Duckworth, expressed a feeling of pity for the small minority who were opposed to generally received views on the subject He regretted that the question should have once more been brought up, and trusted it would now be allowed to rest in peace—Dr Kingston Fowler quoted the case of a lad who had a systolic thrill and murmur over the tricuspid area, due probably to tricuspid regurgitation as well as a presystolic murmur and thrill, to be felt alternately Dr Stephen Mackenzie concurred in Dr Bristowe's views —*British Medical Journal*, Nov 12, 1887

Surgical Tuberculosis —40 – Tuberculous affections are very frequently multiple, because *a* When the virus first enters the system it is deposited in different places The multiplicity of the foci in spina ventosa is well known Less consideration has hitherto been given to the acute invasion of tuberculosis with multiple foci developing quickly, one after another, in the different organs and tissues of hitherto healthy persons, in children and adults, and even in old people The persons so attacked often succumb, but they may be completely cured, and remain healthy afterwards

b Or the tuberculosis may become multiple because there are different infections from without, at different times, and independent of one another A patient suffers in youth from tuberculosis of the lymph glands, is affected by tumor albus or an arthrocace towards puberty, and dies in his thirtieth year of pulmonary tuberculosis This is a very usual occurrence, and it cannot appear strange, since the susceptibility to the tuberculous virus is not weakened by the tuberculous disease, and in the majority of cases the individual has a heightened susceptibility for the virus

41 —But there is no ground, in cases of multiple focal affection, for considering the younger foci as having arisen secondarily from the older foci by autoinfection, and for considering tuberculous joint and bone diseases as of a metastatic character, as has been done a good deal of late Thus far this metastatic character has been proved only for the localization of acute miliary tuberculosis (Concerning autoinfection see 37, *b and d*)

42 The operative removal of a tuberculous focus will of course render impossible the originating of an acute miliary tuberculosis, or the farther infection of lymph glands from this point, but it does not preclude the later origination of equally important affections in other places, and does not mitigate the danger of a later pulmonary tuberculosis A person that, for example, in youth has undergone an amputation of the thigh on account of a tuberculous knee-joint affection, remains endangered for ten or fifteen

years, or at least there is something to apprehend, because the susceptibility to the tuberculous virus is shown in him, and possibly, though not necessarily, still exists

43 Local recurrence after operations in tuberculous affections, and the fact that wounds again become fungous, find their grounds not in the constitution of the patient, in the tuberculous or scrofulous diathesis, as is generally supposed, they are much oftener due exclusively to the fact that the operation was not clean, and that tuberculous tissue was left somewhere, which afterwards again grows out and infects the healthy granulations tissue and cicatrix

After amputations in completely healthy parts, even in persons with advanced tuberculosis of the lungs, recurrence at the stump (fungosities of the amputation wound) do not occur On the contrary, the dry tissues of the emaciated limbs easily heal in such cases by first intention It is a matter of consideration, therefore, that when an amputation is done no fistula should be left in the flaps

Nor have I ever seen in a scrofulous child or in a tuberculous one, even with manifest pulmonary phthisis, the wounds becoming fungous after an amputation on account of trauma or after the extirpation of a lipoma, etc , or in case of a wound, or an extensive laceration of the soft parts that required months to heal, or in case of a compound fracture And I would ask whether any one has ever seen such a thing The report of such a case, observed and thoroughly examined, would be of considerable importance

44 In spite of all this the greater number of all tuberculous joint and bone affections is certainly to be referred to traumatic causes, not necessarily to severe wounds, but to slight trauma, contusions, distortions, that would be followed by no such result in persons who are not susceptible to the tuberculous virus That sprains of the hand and foot frequently lead to tuberculous joint and bone affections (caries) cannot be doubted But even spondylitis usually develops in children after such cases, or after a push, etc It must be supposed that after a severe trauma (subcutaneous fracture, large wound, etc) the energy of the reactive and reparative tissue-proliferation is so considerable that the development of the tuberculous germ is not allowed—an hypothesis for the admission of which the conduct of the lower organisms furnishes many analogies On the contrary, a slight trauma easily furnishes a favorable soil for the development of the tubercle bacillus — *Langenbeck's Archiv*, Bd 33, Hft 1

(*To be concluded*)

AMPUTATIONS FOR DIABETIC GANGRENE —KONIG summarizes the practice of German surgeons as follows In diabetics the tendency to inflammatory and necrotic inflammatory process is greater than in healthy persons Roser and others have pointed out that necrotic processes occur more frequently even in apparently strong diabetics, and those without thirst and polyuria In all cases in which spontaneous or even post-traumatic phlegmonous and gangrenous processes develop, the urine should be examined for sugar This rule does not overlook the fact recognized by Redard, that in such conditions sugar and albumin may be present transitorily According to Roser inflammation and necrosis in diabetics must first be treated constitutionally The question of such larger operations on diabetics, as amputation for gangrène is a difficult one for the surgeon, and the general plan has been to avoid them as long as symptoms of diabetes continue General antidiabetic and local antiseptic treatment suffices in some, but in severe cases the trouble often ends fatally

In such a case last year Konig concluded to risk amputation, and saved a gouty old man (of 70 years) with gangrene of the leg This began at the little toe, and, extending to the ankle, led to suppuration, increase of sugar in urine (from 2 to 4 per cent), loss of appetite and flesh, coma, etc As the patient was in an exhausted condition constriction was employed Rapid amputation at the middle of the leg was done Very extensive arterio sclerosis with calcification of numerous small arteries was found By the next day sugar had disappeared from the urine, and the apathetic condition had passed off The wound remained aseptic, appetite returned Diet was continued and the patient was discharged in eight weeks with no sugar in his urine Later, however, despite antidiabetic regimen, sugar was again found in the urine

A second case was that of a well nourished brewer, æt 40 years, who had phlebitis of left leg two years previously, and thirst and loss of flesh for nine months Gradual development of gangrene of left big toe, with consequent phlegmons of the foot, loss of appetite, continuous hiccough, low fever The urine contained 4 per cent sugar and a trace of albumin Despite careful general local treatment the patient grew worse, although the sugar diminished to 2 and $\frac{1}{5}$ per cent Operation as in the previous case In four days the sugar had disappeared from the urine, and other morbid symptoms were no longer present Discharged cured in six weeks Here also the same arterial changes were found as before Six months later the urine contained no sugar

Konig concludes from these cases that in diabetic gangrene where, despite antidiabetic and local antiseptic treatment, the general and local symptoms do not improve, and further waiting involves danger to the patient, we should try to save life by a radical operation—usually an amputation—executed with the most scrupulous attention to antisepsis — *Centralbl f Chirgie*, No 13, 1887 —*Annals of Surgery*, August, 1887

RETENTION OF URINE PRECEDING APOPLECTIC ATTACKS —MR W GEM reports the following cases

W S , aged 60, laborer, of temperate habits Has had rheumatic gout for some years Was admitted into the infirmary in 1882, and has been readmitted off and on ever since for rheumatic gout Heart sounds normal, but has atheromatous arteries Has had iritis, but no other defect of vision Urine nor-

mal Suffered from retention for six days, after which he had a severe apoplectic attack, with consequent left hemiplegia

C E, aged 40, carman Intemperate Had rheumatism for some time Was admitted in 1882, and has been readmitted off and on ever since for rheumatism and cardiac valvular disease Has albumen in urine, but sight is good Had retention for seven days, followed by an apoplectic attack and right hemiplegia

W C, aged 57, laborer Intemperate Had rheumatic gout for some years Admitted for such in 1885 Heart sounds normal Double optic neuritis, but urine normal Had retention for ten days, after which he had a severe apoplectic attack and complete left hemiplegia

G W, aged 49, baker Habits not known Admitted for melancholia, and was transferred to an asylum Being discharged some time after on trial, he was readmitted for subacute rheumatism Heart sounds normal Sight not ascertained (too restless) Urine normal Had retention for four days, and and then had an apoplectic attack, with subsequent right hemiplegia

All the above cases were treated as follows Perfect rest, blistering the nape of the neck, croton oil, and warmth to feet, *plus* the following drugs bromide of potassium, decoction of aloes, and compound spirits of ammonia, followed up afterwards with the iodides The very best results were obtained by this treatment, with the exception of the last case, which is recent

It is with reticence I bring forward the above cases, as such may have been discussed in the ephemeral literature of the day The drugs above mentioned need no comment from me, as their actions are too evident, but I may say that I have had the most favorable consequences from them in two cases I anticipated, where retention had been complete for two or three days The query of course arises, Would such cases have gone on to an apoplectic attack? I have every reason to suspect such an unfortunate accident, as the one patient had an intense localized headache, with retinal hæmorrhages, the other not so well marked The first one was readmitted after some time with a recent hemiplegia, showing that such an untoward event had previously been warded off—*Lancet*, Nov 19, 1887

Principles of Plastic Surgery—In an article on plastic surgery Mr C B Keetley says It will be granted that all parts of the body are susceptible to septic inoculation, therefore one of the first rules of plastic surgery should be *Thoroughly disinfect the parts to be operated on, the hands of surgeon, assistant and nurse, the instruments, sponges, ligatures, sutures and dressings*

As a preliminary to the use of such germicides as sublimate and carbolic acid, a prolonged washing and scrubbing with the liquid potash soap of Dr Duncan, of St Petersburg, is very useful This soap has two excellent properties, (1) it is an extraordinarily powerful solvent of dirt, (2) it is itself instantly soluble in cold hard water or antiseptic lotions so that it may be said to promptly "do its business and go about its business" But, bearing in mind that in plastic surgery, one almost always desires union by the first intention, and that irritants such as the stronger germicides are not favorable to that, *an ideal plastic operation should be aseptic rather than antiseptic* For this reason I generally, while keeping the instruments in a tray of carbolic, dip them into a basin of recently boiled, not boiling water[1] before touching the patient with them But when they are even temporarily laid down again, it should be either into the tray or upon a damp carbolized towel, disposed around or near the site of the operation The same recently boiled, not boiling, water, is used as a douche and for the sponges Some persons would prefer boracic lotion I greatly doubt whether it has, for these purposes, any advantage over the boiled water If the operation were to occupy days instead of say half an hour, it would be a different matter

With regard to ligatures, they should scarcely ever be used in a plastic operation Temporary pressure with sponge or forceps almost always suffices to check hæmorrhage The boiled water used at a temperature of about 120° will assist Hare lip pins or silver sutures can be often arranged to not only adjust the parts but also at the same time to control an obstinate vessel The objections are manifest to a number of catgut knots in a wound where perfect antisepsis is impossible

I believe it may be laid down as an axiom applicable to surgery in general that *even with the aid of antiseptics, the difficulty of obtaining union in a wound without suppuration increases geometrically with the length of time a foreign body is left unabsorbed in the wound* I may not be expressing myself properly, but I mean, for instance, that when in a simple osteotomy, even though it be done antiseptically, a large splinter of bone be chipped off, and left *in situ*, suppuration is ten times more likely than if no such splinter had been made Very probably it is the case that, even with carefully applied antiseptics, a few germs find their way alive into the wound, but their chance of surviving and multiplying depends mainly upon their finding or not finding some dead or half dead organic nidus to receive them It is, therefore, particularly desirable to keep catgut out of wounds when complete antisepsis is not only difficult but often impossible

As a prophylactic against tedious and troublesome hæmorrhage, the preference of scissors to the knife for the division of all structures except occasionally the skin itself, is to be strongly urged With regard to the skin, in dividing it the precision attainable with a sharp scalpel recommends the latter—*Annals of Surgery*, August, 1887

Hysterical Coma and the Treatment of Hysteria—Dr Wallace A Briggs, of Sacramento, after recording an interesting case, concludes as follows The treatment should be directed to (1)

[1] A handy way in which I think aseptic as distinguished from antiseptic water could be quickly produced, would be by adding iodide of potassium to sublimate lotion until all the mercury was precipitated, but I have never tried this plan

the removal of all sources of eccentric irritation and of emotional disturbance, (2) the stimulation and building-up of the will and higher intellectual faculties, (3) the restoration of the general health and the improvement of the nutrition of the nerve tissues

1 In children, in women, and perhaps no less in men also, especially in those of a nervous temperament, we constantly observe a notable increase of irritability of the nervous centres, in consequence of indigestion This irritability finds expression quite as often in peevishness, in ill-temper, in cynicism, in hypochondriasis, in melancholia, and in pessimistic views in general, as in neuralgia, in perversions of sensibility, and in anomalous and uncontrollable muscular movements When dependent on indigestion, this irritability is the product in part of reflex action resulting from local irritation of the gastro-intestinal tract, and, in part, probably in greater degree, of malnutrition of the nerve tissues, as well as of their poisoning by the products of decomposition

Judging no less from experience than from analogy, I am convinced that the exciting, if not the predisposing, cause of hysterical outbreaks, emanates not infrequently from the digestive organs Regulation of the digestive functions, then, is of the first importance, not only in the removal of eccentric irritation, but also in the prevention of poisoning and the promotion of nutrition of the nerve tissues Displacements and congestive and inflammatory conditions of either the uterus or the ovaries are occasional sources of peripheral irritation, and should be corrected Emotional disturbance in ill regulated nervous systems is often the immediate exciting cause of an hysterical attack, and, whether of sorrow, of chagrin, or of immoderate laughter, should be studiously avoided

2 The psychical and nervous inco-ordinations of hysteria demand strict discipline of the intellect and will The dominance of the will must be asserted until self-control becomes a habit If spontaneous control is impossible, the will power may be effectually stimulated by the interrupted current Its virtue consists chiefly in in its profound physical as well as moral impression It should be rapidly raised to the *effective* strength, and be re-inforced by all the moral influences that circumstances suggest.

3 Morbid conditions associated with hysteria should receive appropriate treatment Cachæmia, which in its various forms, seems not infrequently to sustain a causative relation to the finer organic lesions of the nervous system, demands particular attention Iron, lime, soda and potash salts, especially in the form of phosphates or hypophosphites, strychnia, quinia, arsenic and cod-liver oil, judiciously alternated or combined, are our most trustworthy reconstructive tonics, but they must not be prescribed to the neglect of a proper dietary Strict hygienic discipline should be maintained all along the line—intellectual, moral, physical —*Sacramento Medical Times*, December, 1887

CREOLIN VERSUS CARBOLIC ACID AS A DISINFECTANT AND ANTISEPTIC —DR E VON ESMARCH, assistant in the Royal Hygienic Institute of Berlin, has made a series of experiments with creolin, a new disinfectant, which has been highly spoken of by Professor Frohner, of the new Veterinary School of Berlin Dr von Esmarch made a number of comparative observations with carbolic acid on the disinfecting, deodorising and antiseptic properties of creolin Amongst other observations, he noted the effects of the two substances on fluids containing cholera, typhus, and anthrax bacilli As a rule, creolin appeared to be much the more active Similarly the offensive smell of various putrefying liquids was controlled much more readily by creolin than by carbolic acid Creolin soap, too, showed itself more active as a disinfectant than corrosive sublimate soap —*Lancet*, October 15, 1887

CONTINUOUS IRRIGATION WITH HOT WATER IN SEPSIS AFTER LAPAROTOMY —DR HAGGARD, of Nashville, reports a case in which, after partial removal of a fibroid tumor of the uterus, necrosis of the remainder and sepsis occurred, treated by continuous irrigation for a week with water at a temperature of 105°, and the free use of tonics Recovery and cessation of all previous symptoms ensued He adds the report of a case of laparotomy for cyst of the broad ligament, in which sepsis occurred, owing to the presence of necrotic tissue, whose removal was impossible in the exhausted condition of the patient

Constant irrigation with hot water for twelve days resulted in maintaining the elimination of noxious material, and the patient recovered In both cases the usual methods of drainage failed —*Southern Practitioner*, November, 1887

TREATMENT OF THE THIRD STAGE OF LABOR — FREUND, of Strassburg, gives his conclusions regarding this subject as follows In normal cases a judicious combination of the expectant and active method in treating the placenta and membranes is best In removing the placenta the accoucheur should wait until the first signs of spontaneous expulsion appear In cases where the placenta must be removed at once, Credé's method of expulsion is the best Freund has observed, in normal cases, that the uterus rises toward the umbilicus when it expels the child He imitates, with one or both hands, this action in securing the expulsion of the placenta by gently pushing the uterus upward, and compressing it at the same time —*Deutsche medicinische Wochenschrift*, October 27, 1887

NERVE SUTURE —MR CROFT reports in the *British Medical Journal*, of October 8, a case in which the tibial and femoral arteries and the posterior tibial nerve were cut, the nerve being severed The ends of the nerve were retracted an inch and a half They were carefully sutured with very fine silk, and the wound dressed antiseptically In twenty four hours sensation was established all over the foot, though modified in character on the sole In five weeks the leg was entirely well, and the patient, a boy, had perfect use of and sensation in the foot and leg

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

MEDICAL LEGISLATION

The season of the year is near at hand when a large number of the State legislative bodies will be in session for the making or revision of laws in their respective States, and it is probable that the usual number of bills will be introduced proposing to regulate either the education or practice of the profession, or the sanitary interests of the people, or all combined During the last ten or twelve years there has been an increasing disposition shown by the Legislatures of many of our States to legislate on these important interests This disposition has originated in part from a better appreciation of the value and necessity of sanitary measures for the removal of the causes of many preventable diseases by the people, and in part from the efforts of the profession to establish and enforce a higher standard of education for those proposing to practice medicine, as the best mode of checking the tendency to overcrowd the profession, and at the same time secure for the sick more skilful attendants That these several objects are of sufficient general interest, and so directly affect the welfare of all classes of people, as to merit the careful attention of the legislative bodies, will be admitted by all enlightened citizens

And yet the history of past legislation regarding them, from the first organization of our State legislative bodies to the present time, presents a diversity and instability of character hardly equalled in relation to any other public interest While there is going on a free and frequent migration of physicians from one State to another, and large numbers of students annually graduating in the medical colleges in one State and locating for practice in other States, each State has its own laws relating to both medical education and practice, each differs in some respects from all the others Yet it would be difficult to find among them all a single example of medical legislation founded on correct principles and sufficiently complete in the details to be efficient in securing for the people of the State a sufficient number of thoroughly educated medical men, and at the same time in protecting the sick from the depredations and impositions of ignorant and unprincipled impostors

If these efforts to procure legislation for regulating medical education and practice in the several States are to continue, the first and most important object to be accomplished is the framing of a bill based on sound principles of political economy, brief and simple in its details, yet sufficiently comprehensive to establish and secure the practical enforcement of a fair standard of general education before the commencement of medical studies, and a reasonably thorough knowledge of all the recognized branches of medicine, including clinical and practical laboratory work, before receiving a license to practice, by an able committee, appointed by the American Medical Association And if, after full consideration by that National representative organization of the whole profession, its provisions were approved by a practically unanimous vote, efficient measures should be taken to have its provisions urged upon the attention of every State Legislature whenever medical legislation is attempted, until such legislation in all the States becomes both efficient and practically harmonious Some disposition to act in this direction has already been manifested in connection with the National medical organization At the annual meeting of the American Medical Association in New Orleans, 1885, the subject of legislation for the regulation of medical education and practice was actively discussed in the Section of State Medicine in connection with the draft of a bill presented by Dr John B Roberts, of Philadelphia A resolution was adopted by that Section, asking the Association to direct the Permanent Secretary to communicate a copy of said bill to each of the State Medical Societies and solicit their action thereon The movement failed to elicit any general attention or approval by the State Societies, and two years later, at the annual meeting of the Association in Chicago, a discussion of the subject was resumed in the Section of State Medicine which resulted in the adoption of the following resolution, offered by Dr P H Millard, of Stillwater, Minnesota

"*Resolved*, That a committee of five be appointed by the Chairman of the Section, to frame a *bill* for

recommendation to the several States for regulating the practice of medicine "

In obedience to this resolution the Chairman of the Section, Dr Geo H Rohé, of Baltimore, announced the committee as follows Dr P H Millard, Stillwater, Minnesota, Dr H A Johnson, Chicago, Illinois, Dr R H Plummer, San Francisco, California, Dr C W Dulles, Philadelphia, Pennsylvania, Dr C B Belt, Boston, Massachusetts

The committee was well selected, and we trust that it will be able to report, at the coming meeting of the Association in Cincinnati, a bill or form of law much better adapted to accomplish the objects desired than any other heretofore proposed or adopted The committee should be encouraged and aided, in its important work, by a candid discussion of the more important topics and interests involved, by the medical press

THE ACTION OF DRUGS ON THE KIDNEY

The action of drugs on the circulation and secretion of the kidney is a subject as interesting as it is comparatively little known A brief and valuable contribution to the subject was made by DR C D F PHILLIPS, of London, to the Ninth International Medical Congress, and published in the *Lancet*, of November 12, 1887 The experiments were made on cats and dogs The results arrived at may be summarized as follows

The effects of caffeine citrate, in half-grain doses The *blood-pressure* is first lowered, and is then raised, both effects being of short duration and slight, especially the rise of pressure The *heart* showed first a diminution in the force of the beats, followed by a slowing, with beats of markedly increased force On the *kidney* caffeine causes at first contraction, lasting two or three minutes, and accompanied by diminution or even arrest of secretion, this is followed by expansion, that lasts, after a one-grain dose, more than half an hour sometimes, the flow of urine being at the same time trebled That the effects on the kidney cannot be due to the changes in the general blood pressure, is shown by the fact that they do not occur simultaneously

The effects on the general blood-pressure are slight, and last only a few seconds, the effects on the kidneys being measured by minutes

Ulexine, the new alkaloid obtained from the seeds of the common gorse, acts in a similar way to caffeine The objection to it is that its diuretic action is maintained only by doses that would either kill or produce violent convulsions Like caffeine, it produces first a constriction and then an expansion of the renal vessels, with diuresis It differs from caffeine 1 In being more powerful 2 Its effects are more transitory 3 Repeated doses of caffeine injected rapidly cause only contraction of the kidney, not followed by expansion, a similar excess of ulexine causes expansion only, without contraction Other substances that cause expansion of the kidney are dextrose urea, acetate and chloride of sodium, and probably all constituents of the urine. More numerous are the drugs causing constriction of the kidney Digitalin causes contraction in doses of $\frac{1}{40}$ gr , which persists for as much as half an hour While it is difficult to say if digitalis is a true diuretic, or only exerts its effects through the heart, the urine is not diminished during the contraction of the kidney, as is the case with caffeine, but it is generally increased The explanation probably lies in the effect on the general blood-pressure, digitalin raising and caffeine lowering it

While spartein acts similarly to digitalin on the heart, general blood-pressure, and renal vessels, it causes a great diminution of urine, and its so called diuretic effect, in disease, is due to improvement of the general circulation The chief action of strophanthin and apocynein is on the heart muscle, and they produce little or no effect on the peripheral vessels Turpentine, adonidin and barium chloride produce marked renal contraction without diuresis

From the above it is seen that "reputed diuretics more commonly produce contraction of the renal vessels than expansion Further, that expansion is either slight, as by acetate of soda, or, if large, as by citrate of caffeine, it is only produced by small and initial doses The powerful action of alexin on the respiratory mechanism is a great drawback to its use, one-sixth of a grain was used in our experiments, but one-twelfth of a grain would completely arrest respiration Then, again, such drugs as produce contraction of the kidney cannot be bracketed together, since, though they all have the same effect on blood-pressure, digitalin alone has an obviously diuretic effect " The flow of urine is not so much dependent on blood-pressure as on the rate of the blood flow in the renal vessels "It is necessary also to remember that although such drugs as strophanthin produce a great increase in the force of the cardiac beats, yet the heart is very much slowed, so that it is possible that the amount of blood sent into such an organ as the kidney in a given time may remain the same, whereas, such a drug as digitalis, producing a rise of blood-pressure and a contraction of the kidney vessels, may cause an increased quantity

of blood to pass through those vessels, and thus it acts as a diuretic Inasmuch as spartein has not a marked diuretic action, we must also assume that digitalin has some peripheral action on the secretory apparatus of the kidney " Dr Phillips concludes his paper by calling attention to the value of the plethysmographic method of experimentation in regard to the action of drugs on the circulation

A NEW DANGER FROM OLD RAGS —A writer in the *Lancet* calls attention to an unsuspected danger from old rags, cloth, and rubbish A lady, the head of a school, found a miscellaneous mass of such stuff in a number of bolsters and pillows that had been in use in the school It seems that the practice of stuffing bedding with such material is very common It is possible that this may account for some of the mysterious outbreaks of infectious diseases in schools and families

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY

Stated Meeting, October 17, 1887

THE PRESIDENT, W T BELFIELD, M D, IN THE CHAIR

DR E FLETCHER INGALS reported a case of

RETROPHARYNGEAL ABSCESS

The following is one of unusual interest on account of the deep fistulous tract which remains, and as an illustration of the necessity for prompt incision for the evacuation of pus in cases of retropharyngeal abscess

Mrs H P, æt 44, was sent to me during the month of August from a neighboring State for an opinion She complained of an oppressive, purulent discharge from the pharynx, with more or less pain between the shoulders, cough and night sweats She stated that the discharge would occur every few days, and that afterwards she would be free from cough, pain or other annoyance for some time, when the symptoms would again come on gradually and increase steadily until another evacuation of the pus occurred

Six months before coming to see me she had been attacked by soreness and swelling in the naso-pharynx The swelling had gradually extended downward, causing more or less difficulty in swallowing and respiration, and had been allowed to take its course for two months, when an opening was made in the lower part of the pharynx which gave vent to a large quantity of offensive pus Subsequently the incision closed, was reopened twice, and finally it had remained patent While the swelling was still in the naso pharynx she had for some time also a purulent discharge from the right ear I found the patient anæmic, weak and emaciated, weight only 94 pounds, instead of 112 pounds when in health Pulse 132 Tongue red and glazed in centre, but the appetite good The cough was not constant, but it usually troubled her considerably every day The pains of which she complained were not severe and were confined to the chest and shoulders

Upon examining the chest I found no abnormal signs excepting slight feebleness of the respiratory sounds over the lower third of the right lung A mucus polyp half closed the right naris, larynx normal When the tongue was forcibly depressed I could see, a little to the right of the median line, at the lower third of the larynx, a small red fungoid mass, about the size of a pea. The vault of the pharynx was normal, and nothing else of an abnormal character could be seen I removed the fungoid mass with a snare, and beneath it found an opening about two millimetres in diameter, into which I passed a small elastic catheter, which I gently pushed down the fistulous tract thirty centimetres, when she complained of its extremity causing her pain a little to the right of, and below the right breast

The position of the lower end of the fistula seemed in some way to account for the enfeebled respiration at the lower third of the right lung The patient did not wish to remain in the city, I therefore was unable to see her when there was pus in the cavity, and consequently could not determine the exact position of the lower end of the fistula

I recommended removal of the polypus and washing of the fistulous tract daily with carbolized water or peroxide of hydrogen through the catheter introduced to its bottom Tonics were also suggested The result of the examination was communicated to her physician, but I have heard nothing further of the case I was under the impression that when the lower part of the sac was filled with pus it might be possible to detect it and make a counter opening through the pleural sac, whereby constant drainage could be established so that healing of the fistula might be effected

DR F O STOCKTON said It seems to me that this sequel of a retropharyngeal abscess is something a little out of the ordinary run I must say that in my experience I have never met with anything that has produced any such symptoms, although I have frequently met with fistulas resulting from a retropharyngeal abscess The case is interesting as showing what may occur when an abscess of this kind is not recognized in time Abscesses are liable to burrow deeply, and in a location like this where the soft tissues overlie a hard, bony substance, an abscess with a tendency to burrow could easily go very deep and by pressing upon the nerves produce these pains, but it seems strange, unless the nerves were bare, that passing a small catheter down should produce these pains below the right breast It looks as though some of the spinal nerves might have been laid bare by this burrowing of the pus In a case of that kind I think what the doctor suggested was about the only thing that could be done, although I

can hardly see how the opening he suggested could be made so as to give thorough drainage without injury to some nerve or other important structure

DR W E CASSELBERRY said that the subject is one of interest for two reasons, *first*, retropharyngeal abscess is not a common disease, especially in the adult It is oftentimes overlooked, and the responsibility rests upon the physician in all cases where there is dyspnœa, continuous or paroxysmal, to make a thorough examination of the throat both by inspection and palpation, in order to determine the diagnosis *Secondly*, it is of interest on account of the peculiar complication in this case I have seen the record of a similar case reported by Cohen among a number of cases of retropharyngeal abscess having some peculiarities In this one a sinus burrowed deeply between the œsophagus and trachea and finally pointed externally low down in the neck, and pus was evacuated by incision On account of the loose connective tissue in this region and the influence of gravity, the natural tendency is for the pus to burrow downward and other cases of the sort will doubtless be observed

In reply to Dr Strong as to how he would make the opening suggested, Dr Ingals said I thought that when that sinus was filled with pus there might be a considerable collection, a pocket perhaps of a couple of inches in diameter, and if it was of that size I could find the location and when found, I believed I could get into it I should not hesitate to plunge an aspirator needle into it, even passing it through the lung if necessary I am reminded of a case in an infant that I saw so many years ago that I am not ashamed to tell of it—I then thought the child died of convulsions, but I think now that it died of retropharyngeal abscess I know from reading of these cases that in young children sudden stopping of the breath occurs that seems as if from closure of the glottis, but there is none of the sound that occurs with spasm of the vocal cords Last week I had a man of perhaps 50 years of age sent to me, the word that came with him was that he had stenosis of the larynx and that something must be done I took my laryngeal mirror to examine his larynx and found a large swelling in the pharynx which I could see by depressing the tongue It was a retropharyngeal abscess which had existed four weeks He swallowed with difficulty, but opening of the abscess relieved the dysphagia

DR A B STRONG read a paper on

SUBPERIOSTEAL RESECTION OF A RIB FOR EMPYEMA IN CHILDREN, RECOVERY

(See page 779)

DR E FLETCHER INGALS Some four years ago I reported fourteen cases of empyema I had treated, and since that time I have treated a number of others I have had no experience with the method adopted by the reader of the paper, but one of my patients unfortunately had the operation done upon him I have not very much sympathy with the operation excepting as a last resort to allow of greater contraction of the chest The author of the paper performed the operation skillfully and his patients recovered, I fear if I had performed it my patient would have died But I can open the chest otherwise with safety to the patient and satisfaction to myself I have treated several cases of empyema similar to those just reported, one very young child, perhaps a year and a half old, where recovery followed simple aspiration I recall two others which were similar to the first case reported, in which the disease had run from three to five weeks Drainage tubes were inserted through a trocar, and the cavity washed out frequently, and in both the drainage tubes were required only between one and two weeks, and the patients were well within three weeks I think they recovered more speedily than they would have done if the rib had been resected Another case I have in mind had been sick longer, two or three months, when I first saw it, and it was perhaps six weeks before the child recovered In all of these cases the expansion of the lungs and chest wall became perfect

I think children are quite as likely to recover by this method as when ribs are resected, and I think we avoid a great danger I feel confident that I have seen cases die from free opening in the chest cavity, and I do not think it a wise practice to open the pleural sac in this manner However, I have seen two cases die within a few hours after simple aspiration, but I do not know whether the removal of the pus was the cause of death or not One was a child who had been suffering from scarlatina and was so nearly dead that she did not feel the puncture of the needle, and the other was an aged man In the case reported of the boy 17 years of age, I think drainage tubes would have acted quite as well introduced through a trocar, though not quite as large tubes could have been introduced, but I do not think such a large tube necessary With two drainage tubes one-eighth of an inch in their inside diameter I think there is no difficulty in washing out the chest and doing it thoroughly

One point spoken of in the paper I am glad came up, as it brings to mind something important in the operation, that is do not operate too low In this case the 9th rib was resected, if it had been the 6th or 7th rib there would not have occurred the trouble which was experienced afterwards I have had the same trouble through the introduction of drainage tubes too low One patient in whom the tube was introduced in the 7th or 8th interspace near the angle of the rib wore it several months, but finally died of pneumonia of the opposite lung, and on examination I found the drainage tube for two inches in its course upward bound to the chest wall by the diaphragm which had crowded upward My rule is to make the opening within an inch and a half of the surface of the fluid when the pleural sac is about half full, if the cavity was filled I should go between the 6th and 7th ribs, or the 7th and 8th near the angle The method that I have used in introducing drainage tubes would perhaps be of some interest At present I use a broad flat trocar that is wide enough to allow the introduction of two of these tubes at once, that is two tubes with an inside diameter of one eighth inch First making a very

small opening in the skin with a scalpel, the trocar is then plunged in the cavity, and as the stilet is with drawn, I place my thumb over the canula to stop the flow of pus, the tubes that have been prepared be fore hand, are then slipped rapidly through the canula to the required depth, and the canula is at once withdrawn No air will have entered the chest and not more than two ounces of pus will have escaped To make the tubes I take a piece of two feet in length, cut it half way across near the middle, fold it on itself and stitch the two sides together so that the tubes can be spread apart in the chest In one of these tubes I make openings for about four inches, in the other one or two openings close to its extremity The outer ends of the tubes are tied tightly so that the pus will not flow till I am ready to fasten the tubes in I cut off two half inch sec tions from the same tubing and pass through each two bits of string, the ends of which are tied in loops, these are carried over the drainage tubes down to the surface of the chest, long strips of ad-hesive plaster are then passed through the loop and fastened to the chest when the tubes will be firmly fixed I then carry a rolled bandage around the chest over the strips and the dressing is complete If the patient is in good condition, I then at tach to each drainage tube by means of a bit of glass tubing longer sections of tubing which have been filled with water, that can reach to the bottom of a basin of water sitting on the floor, the strings which have fastened the ends of the drainage tube are then cut and the pus allowed to escape, or such part of it as is deemed advisable I recall one case in which I am satisfied if I had allowed any quantity of pus to escape at first it would have been fatal On one or two occasions I did allow more to escape than was desirable and I had to inject water into the chest to replace it

The after treatment that I have employed consists mainly in washing out the chest twice a day with a solution of carbolic acid 2 per cent at 100° F With tubes placed in this way the patient's friends can perform this office, and the physician will not be obliged to see the patient but a few times, once a week or once in two or three days, according to the intelligence of the attendants I think, however, that in adults where the lung expands with more difficulty, one should be very careful to watch the case about the fifth or sixth week to insure final closure of the cavity I have seen cases in which at this time I think the closing up of the cavity ceased from lack of proper stimulation It is very easy to measure the size of the cavity by filling it up with water and measuring the water as it flows out At first the cavity will rapidly diminish in size, but after two or three weeks it closes more slowly, and after the fifth or sixth week the healing will cease in some cases At this time I have used satisfactorily washes of solution of the sulphate of zinc or copper, I like best the sulphate of zinc In two cases of adults where I could not watch them closely at this time, I have had some difficulty later on in closing the cavity I stated in the beginning that I had per-sonal experience in only one case in which resection of the rib had been done The patient had been sick about two years when I first saw him I intro-duced the two drainage tubes as described and the cavity closed until it would only hold about an ounce, but there seemed no way to get this cavity to heal, however, the gentleman was satisfied and went about his business, until finally he fell and broke his arm and went into the hospital While there it was concluded to resect one of the ribs so as to allow the cavity to close entirely In resecting the rib an artery was cut, and the surgeon had great difficulty in stopping the hæmorrhage The resec-tion did no good though larger drainage tubes were introduced, they did not cleanse the cavity better than the smaller ones, and the man still wears them From my experience I believe that where two tubes are introduced as I have directed, and washing is carried out through first one and then the other, there is no difficulty in cleansing the cavity per fectly, unless gangrene has occurred Flakes of lymph will be readily washed out, or if too large they will be disinfected so as to remain harmless until they finally break down or become organized with the new tissue that binds the two pleural surfaces firmly together

DR JOHN D SKEER I have not had much ex-perience in exsection of the ribs for drainage pur-poses, but as far as the operation is concerned it is certainly not a very formidable one when performed as Dr Strong has described it, by making the oper-ation subperiosteal I have had a great deal of trou-ble, in my practice, in the drainage of chest cavities with small drainage tubes I recall a number of cases in the army, and I think now that if I had those cases under my care I would exsect a portion of the rib The rapid flow of matter under these circumstances does not necessarily follow The opening into the cavity may be small or large, ac-cording to the size of the drainage tubes, and the flow of matter can be moderated according to the requirements of each individual case The impor-tance of this grows out of the fact that the lung be-comes bound down by bands and adhesions which prevent its rapid expansion, and there may possibly be ulcerated spots admitting air into the pleural cav-ity, and pus into the lung tissues, from a too ready expansion of the lung, and it takes time for these bands and adhesions to soften down, relax and ex-pand to accommodate the lung in its natural expan-sion We should differentiate between *serous effu-sion* into the pleural cavity and suppurative inflam-mation of the pleura

DR H T PATRICK My experience with this operation of resection is limited to one case, which I had under observation three years ago It was not a case of simple empyema, but a pneumo pyo-thorax of a boy ten years of age, of over a year's standing, with considerable retraction of the chest, and a small external opening Three ribs were re-sected, the 6th, 7th and 8th The ribs were mark-edly overlapping one another, and for that reason more were removed The boy made a very satis-factory and rapid recovery, he had considerable temperature and was much emaciated, but immedi-

ately after the operation, the chest being washed out once a day, he lost his temperature and at once began to flesh up, and in a few weeks was entirely well In regard to the operation, my idea is that it should be limited to this class of cases I should say that in empyema aspiration, incision and drainage, and resection of the rib, should be the order of procedure In Dr Strong's second case the lung failing to expand well points out one of the weak points of the operation as a primary procedure Had aspiration been performed first I think the conditions would have been more favorable for expansion than by making as free an opening as for resection and allowing air to enter the cavity I think we follow right in the line of Nature's efforts in these cases of retraction of the chest wall, we allow the chest to fall in and approximate itself to the other surface There are other dangers connected with this operation as a primary procedure, one is that there are cases on record where, under an anæsthetic, the cavity has ruptured into a bronchus, and the patient has choked to death Deaths have also been recorded from simply washing out the cavity

DR N H PIERCE There is one thing that I would like to suggest in this connection, and it is this As I understand it, we resect a rib to simply enlarge our area of drainage In a case that I had in the last month where I had drawn off nearly three gallons of fluid in three *tempos*, I first merely inserted a drainage-tube one-half inch in diameter, this drain was constantly being plugged up by coagula, or whatever it might have been, thus causing retention and absorption of the purulent matter, followed by the usual symptoms I resected a rib after that and introduced a drainage-tube one inch in diameter, with the advantage of not having it clogged up again, the patient is making a good recovery Another point is, that there have been a number of cases reported from the Berlin clinic, of death from drowning occurring from washing out the cavity while the patient was under ether, there being a communication between the pleural cavity and the lungs It is well, therefore, that the primary cleansing be delayed until the day following the operation I have, in three cases of this character, let out the entire contents of the cavity, amounting in each case to three or four pints, with no abnormal result Using as an antiseptic lavage a saturated solution of boracic acid There have been deaths reported from the use in the pleural cavity of carbolic acid, thymol and salycilic acid, and the only agent that has not been proven more or less dangerous when used in the pleural cavity is boracic acid, and Dr Fraenkle insists that this is the only thing that should be used in this capacity

DR A B STRONG was very glad to find that his article had excited so much interest It is certainly a practical subject, and one we are likely to meet with any day, and I am yet in favor of resection It is my impression that the first resection was made about fifteen years ago A point against resection was raised by Dr Ingals—that of the too rapid evacuation of the matter That point was ably answered by Dr Skeer, who said that when we have free evacuation we have a corresponding influx of air which takes the place of pus I believe that to be so In the two cases reported there was considerable cough at the time the chest was opened, but that quickly subsided I had no fear that there would be rupture of the lung, I could feel the pleura three fourths of an inch thick Until some better reasons are given for not operating, I shall certainly be in favor of making a free opening by resection I want to make an opening large enough so that I can get into the cavity and evacuate it freely, I cannot get out enough pus through an eighth of an inch opening to satisfy me In the case of the older boy, shreds of lymph as large as the little finger were thrown out for several days I have no fear in opening the chest freely and draining it freely

(*To be concluded*)

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, October 6, 1887

THE PRESIDENT, THOMAS M DRYSDALE, M D, IN THE CHAIR

(*Concluded from page 761*)

DR H A Kelly read a paper on

PALPATION AND SOUNDING OF THE FEMALE URETERS,

in which he stated that he made it his routine practice to examine all gynecological cases with reference to the condition of the ureters Since Dr Sanger had demonstrated to him in the summer of 1886 the facility with which both ureters could be outlined through the anterior vaginal wall and traced back to the posterior pelvic wall, the speaker had made a long series of confirmatory observations and in some instances demonstrated the value of such observation by finding disease of the ureter Dr Kelly had added to this a method of his own by which the ureter is picked up and handled bimanually, and with the exact knowledge thus gained as to its position, he then proceeds to catheterize it with Pawlik's catheter He detailed a case in which the catheter was thus introduced into the ureter and passed back to the post pelvic wall The urine escaped in little gushes of from 10 to 15 drops every ten or fifteen seconds, evidently accumulating beyond the catheter until the pressure became sufficient to dilate the ureter and let the urine pass down into the eye of the instrument About 3 drachms of urine were drawn in this way, and on removing the catheter, about 5 ounces of urine were drawn from the bladder A disadvantage of Pawlik's catheter is that the sharp eye sometimes catches and tears the mucous membrane of the ureter

Dr Kelly showed some sounds which he had constructed some time since when studying this subject, but considered them inferior to Pawlik's instrument The value of knowledge which may be thus gained was illustrated by reference to a recent case of severe operation, removing adherent, pus containing ovaries and tubes On the second day urine appeared in the

tube and flowed freely The only way of determining from which kidney this flow came is by catheterization of the ureter

Dr Chas M Wilson thought that such an instrument, used in cases with a history of pyelitis, might be the cause of serious trouble He has tried in a number of cases to palpate the ureters by Dr Kelly's method, in a few elderly women he has succeeded, but in nulliparæ with firm tissues he could not distinguish the ureters

Dr J Price considered these methods of examining the ureters of but little practical use, for trouble does not exist in the ureters alone, but in all the pelvic organs and kidneys, and when these are distorted by new growths and inflammatory products it would be very difficult to locate the ureters The case cited by Dr Kelly in his own experience shows how difficult it is, even with the fingers in the pelvis while removing uterine appendages, to locate the ureters through one layer of peritoneum, to say nothing of the conditions when we have to deal with inflamed and thickened vaginal walls

Dr Montgomery thought it would require extreme skill to pass such fine instruments without doing injury to the mucous membrane Dr Bozeman, in a paper read before the Ninth International Medical Congress, recommended dilatation of the ureters and washing out of the pelves of the kidneys and ureters in pyelitis, even advising splitting of the bladder through the vagina in order to reach the orifices of the ureters

Dr Walker was very much interested in this subject and has been desirous of accomplishing this procedure in some patients that he had in his care in the Philadelphia Hospital He had succeeded in palpating the ureters in males, but not in females This ability to pass a catheter into the ureter will enable the surgeon to determine in any given case which kidney is diseased

Dr Kelly offered his services in sounding ureters to any member of the Society interested in following up the subject As for danger, there is none The instrument must be lightly poised between thumb and fore finger and gently passed in, or not at all The sensation when the end of the catheter is caught by the ureter and it begins to pass up the tube is characteristic Dr Walker is certainly correct in his high estimate of the great value of the possibility of sounding the ureters free hand in certain puzzling renal cases As to Dr Price's remark, cases in which there is much pelvic cellulitis are not those in which we desire to sound the ureters Ureteritis is a distinct, well defined disease He treated one case which he cured by opening the base of the bladder The whole trouble lay in the extremities of the ureters The first to suggest splitting the vesico-vaginal septum and rolling the ureteral orifices, and thus under guidance of the eye catheterizing them, was Dr Emmet Pawlik's work was but the culmination of a vast number of attempts to accomplish this, from Tuchmann, who attempted to clamp the orifices of the ureters, and Selbermann, who tried to choke them by a bag of quicksilver, and Simon's dilatation of the urethra, and Noumann and Gruenfeld, who tried to reach it by endoscopic methods Sanger showed how readily the ureters can be palpated, and I think by combining a careful bimanual palpation according to my own method and following this with a free hand catheterization of the ureters already so distinctly located, I have added a method of real value, simplifying this difficult subject It is not true that great skill is required to thus palpate the ureters I can teach any one to do it

Dr Hirst reported a case of

TYPHOID FEVER IN A PREGNANT WOMAN

The impression still prevails in some quarters among general practitioners that typhoid fever will not attack a pregnant woman, an idea originating, doubtless, in the teaching of the famous Rokitansky, who believed that the condition of pregnancy granted a woman immunity from this disease It is unnecessary, of course, to point out the fallacy of this opinion or to refer to the statistics of 322 cases of typhoid fever during pregnancy collected by Charpentier The case that I would report occurred in a young prima gravida who was admitted to the Philadelphia Hospital in the second week of the attack The disease presented all the characteristic symptoms in a typical manner, leaving no doubt as to the diagnosis On the tenth day after her admission to the hospital the woman gave birth to a child which corresponded in its development to the seventh month of intra-uterine life The infant died two weeks after birth but, unfortunately, the cause of death was not ascertained An interesting feature in this case was the effect of labor upon the temperature As uterine contractions began the woman's temperature was 104 2°, but it steadily lessened as labor advanced, until directly after the expulsion of the child it was only 95° Under the influence of external heat and stimulants hypodermatically, the patient reacted and made a good recovery

Dr Longaker remarked that Dr Hirst deserved credit for bringing this subject forward We are perhaps too much in the habit of regarding with suspicion cases of typhoid fever in the puerperal state His experience had taught him that high temperature in typhoid fever in the pregnant woman was incompatible with fœtal life He had been recently associated with such a case which ended fatally

Dr Chas M Wilson had under his care a pregnant woman with typhoid fever in whom the temperature rose as high as 106+° and was not reducible for several hours, but the child survived and was delivered alive at term Numerous similar cases are on record, so a temperature as high as 106 + is not necessarily fatal to fœtal life

Dr Montgomery remarked that in the majority of cases maternal typhoid fever is fatal to fœtal life Premature labor has occurred in all such cases that have come under his notice In one such case the temperature rose to 105° and miscarriage occurred, and was followed by a fall of temperature to 97°, with collapse from which it was very difficult to restore her The temperature again rose to 105°, and after a protracted illness the patient recovered

Dr W S Stewart remarked that in one case of

typhoid fever, about the sixth month of pregnancy, in which the patient became emaciated to a remarkable degree, she recovered and was delivered of a living child at term The temperature did not rise very high

DR J C DACOSTA stated that these cases do not all abort or die He recalled one case in particular with a temperature of 105 5°, with characteristic typhoid eruption and intestinal hæmorrhage, four stools containing each from one to two pints of blood having been passed, which went on to full term, twins being delivered alive

DR HIRST, in closing, stated that although the temperature of his patient remained at 95° for over twelve hours despite all that could be done to raise it, she did not appear in collapse, but looked and felt quite comfortable The prevalent idea as to the danger to the fœtus of high temperature in the mother would appear to be erroneous Runge's well known experiments are often quoted to support the view that the fœtus is in danger if the mother's temperature reaches 104°, but Doléris in 1883 showed that if the maternal temperature is gradually and not quickly raised the fœtus remains unaffected Runge, in a second set of experiments, found that Doléris' conclusions were correct Preyer on one occasion actually found a temperature of 111° in the anus of a living fœtus

DR PARISH considered that the high temperature in disease was accompanied by blood changes which contributed to the fatal result

DR J M BALDY read a paper on the administration of

SALINES IN PERITONITIS FOLLOWING ABDOMINAL SECTION

Twenty five per cent. of the deaths following abdominal section are attributable to peritonitis (Agnew) Taking the hint from Mr Tait, I never take any steps to prevent a movement of the bowels after operation, and routinely administer salines on the second or third day, repeated in small doses, especially when there is distension and persistent bilious vomiting The results following this course have been most satisfactory I have used salines in large concentrated doses, ℥j, repeated several times and aided by large, 2 quarts, turpentine enemata in fully developed peritonitis, with the best results The symptoms begin to subside almost immediately when the bowels commence to discharge watery stools The treatment is in every way preferable to the use of opium, and is logically infinitely better than the narcotic Opium only does good by relieving pain, at times, in enormous doses The bowels are already "in splints" from the disease and do not need the aid of the drug for that purpose Opium, however, does a world of harm It helps keep the bowels in splints and so favors the formation of those great masses of adherent intestine and organized bands which we find so often the cause of subsequent intestinal obstruction Still worse, it closes all the avenues of escape for the poisonous products of inflammation found in this great lymph sac, and in this manner keeps up the inflammation much more surely than the rubbing together of the peritoneal surfaces will With salines, however, an active peristaltic movement is kept up which tends to prevent the formation of adhesions and bands They drain the abdominal cavity of the products of inflammation, and by depleting the blood-vessels of the intestines and peritoneum tend to prevent the throwing out and organizing of lymph to any great extent There are, of course, dangers in the production of large watery stools, but the treatment must be used with care and judgment I would suggest that in the after treatment of abdominal section the bowels be moved as a matter of routine on the second or third day after operation That on the first access of pain and soreness with distension, a brisk purgative be given at once In case a general peritonitis is developed, the production of large watery stools should be secured as quickly as possible, by purgation and stimulant enemata, the amount of purgation to be controlled in accordance with the strength of the patient The salines as suggested originally by Mr Tait are perhaps the best of the purgatives for the purpose

DR WATSON remarked that Mr Tait had been led to the use of salines because he had always observed bloody serum in the peritoneal cavity after death from peritonitis Dr Watson has been in the habit of using saline laxatives whenever he has found signs of beginning peritonitis after labor Once after craniotomy, and again after a very difficult labor he found their use of very decided benefit in cutting short threatened attacks of peritonitis, both cases had good recoveries

DR LONGAKER remarked that Dr Bantock, while in this country recently, had expressed entire want of faith in any benefit to be gained from the use of salines in peritonitis

DR PARISH explained that peritonitis as seen by Dr Bantock was always of septic origin, and the patients would die under any treatment That form of peritonitis is preventable The saline treatment is quite reasonable, it is an adaptation of an old method of treating dysentery and inflammatory diseases of the intestines

DR WALKER had employed salines as depleting agents in various inflammatory diseases When the depletory action is desired, concentrated solutions should be administered A weak solution will act simply as a laxative

DR CLEEMANN had had success and failure with both the opium and saline methods of treating peritonitis Salines had been recommended years ago by Dr Meigs in the treatment of peritonitis Several successive attacks of typhlitis in one patient had been subdued under the use of opium A case of peritonitis under his care had shown progressive relief after every movement of the bowels, the result of a dose of castor oil As the opium treatment has been adopted by the majority of physicians, it is presumably the best

DR KELLY cordially endorsed the general tone of the paper, and believed that serious consequences will often be averted by a timely free depletory purgation He had used calomel and soda, but now

considered salines better All peritonitis is not, however, as the speaker would urge, to be so treated There is a dry form, which I have verified by post mortem examination, which corresponds to the friction dry stage of pleurisy, which is better treated by opium We must bear in mind that the depletion of the intestinal villi only quickens the absorptive activity of the peritoneum, and a large accumulation within the peritoneum may readily be too great to be thus disposed of Here the drainage tube saves lives by disposing of the excessive and often unavoidable serous weeping from wounded peritoneal surfaces I call this my *fifth emunctory*, and it is better than all the natural emunctories in these cases, when properly handled, disposing of accumulations at once, without in the least taxing the powers of the patient Next to the drainage tube the best emunctory is that nearest the field of activity, the intestinal tract, and next, but much inferior to this, come the kidneys, then the skin, and lastly the lungs

Dr Montgomery resorts to closely restricted food and drink and the administration of concentrated doses of salines in commencing or threatened peritonitis He adopted this method at the Med Chir Hospital recently in a case of peritonitis consequent on the presence of a malignant tumor which could not be removed He did not use a drainage-tube, but kept the patient on restricted diet and drink, applied a light bandage and administered salines

Dr J Price thought the preparatory treatment of paramount importance in abdominal surgery After an operation opium is simply harmful, while salines are soothing to the patient and prevent flatulent distension Upon the slightest indication of peritonitis use them freely, and it is simply wonderful what rapid disposition is made of the thirty seven varieties, according to Sternberg, of rhizopods and boa constrictors Again, the drainage tube is of the greatest importance in preventing peritonitis It usually does its work, if managed well, in the first twelve or twenty four hours

Dr Baldy does not think there is such a thing as dry peritonitis The idea of administering salines is to deplete, and concentrated solutions should be used The use of opium by the majority does not prove it to be correct

ST LOUIS MEDICAL SOCIETY

Stated Meeting October 1, 1887

The President, S Pollak, M D in the Chair

Dr W B Dorsett presented the specimens of a case of

CANCER OF THE UTERUS

M N, æt 63, German, widow, mother of five children Admitted to Female Hospital, August 8, 1887, suffering with "general debility," or, as she expressed it, "weakness" About a week after admission she called my attention to a swelling in the right groin Upon examination it was found to be about the size of a walnut, firmly fixed, indurated at its margins, with a small spot in the center which slightly fluctuated Pressure, although firmly produced, caused no pain The presence of this tumor (an indurated gland) led me to make a careful examination All of the external organs of generation were found to be perfectly normal Upon passing my index finger into the vagina, I found it to be only 1½ inches in depth The anterior and right lateral wall hard and unyielding, cervix uteri hard, uterus firmly fixed Bimanual palpation did not reveal the position of uterus, so firmly was it bound down in the pelvis A round tumor similar in size and shape to the gland in the right groin could be felt immediately above the pubes It was so firmly fixed that it could not be moved in any direction A very offensive discharge tinged with blood was issuing from the vagina, a discharge characteristic of cancer of the uterus The examination caused the patient no pain, and upon interrogating her closely, she said she never suffered any pain in that region, and in fact did not know that anything was the matter, except that she was very weak There was this offensive discharge, not very copious, no pain, and no hæmorrhage at any time Her appetite was remarkably good from the time of her admission to the time of her death, 52 days The treatment consisted in nourishing diet, tonics, and, as she was habitually constipated, laxatives As she always slept well, and never complained of pain, no sedatives or hypnotics of any kind were given She grew weaker daily, and died September 29, of exhaustion

Post-mortem examination made by Dr F D Mooney about twelve hours after death Body much emaciated, somewhat pale in color, but not distinctly of characteristic cancerous hue Uterus bound down in pelvis firmly, and was only removed from pelvic cavity with difficulty, and when taken out, the uterus, bladder, vagina, and right ureter and kidney, present this appearance On the posterior wall of bladder is seen a hard tumor, about the size of a walnut, breaking down in center, and is the tumor I felt in making the digital examination Anterior and right lateral vaginal wall hard and thickened, cervix uteri hard and nodulated Right broad ligament much thickened, nodulated and slightly friable Right ovary in the same condition, adhesions very firm between the cancerous (?) mass and right pelvic wall The fundus and anterior aspect of uterus free from pathological changes, posterior aspect of body infiltrated and firmly adherent to cancerous mass The right ureter was found passing down behind the tumor and dilated above the tumor to four or five times its natural size Pelvis of kidney in same condition as to dilatation The most interesting feature in this case was the total absence of pain Lawson Tait, in his work on "Diseases of Women," page 59, states that "This disease is at once the most painful of all the manifold afflictions from which humanity suffers, and the most terrible because nothing can be done for cure, and even our palliative measures are insufficient" And Thomas, in his work in enumerating the varied "symptoms of cancer," heads the list with *pain*.

next comes metrorrhagia in short, all writers I have consulted on this subject agree that pain and hæmorrhage are the chief characteristic symptoms of this disease

In this case they were entirely absent, still the characteristic odor of the discharge was present, and from the odor of the discharge and from the pathological condition (not microscopical) found in the post mortem, I am of the opinion the condition is cancerous

DR HULBERT It was certainly very remarkable that she did not suffer any pain Examination of the tumor shows that the uterus is hardly affected by it, and as to the adhesions existing, I should judge that they had been due to pelvic peritonitis It may be possible that the absence of pain is because it was entirely developed in the broad ligament The cancer coming out so gradually in the loose connective tissues, it made its way without involving any of the nerves, and so the pain would not occur I have been astonished at the amount of degeneration that has occurred from cancer, and the slight amount of pain the patients suffered In two cases I saw the uterus was to a like extent involved

DR LUTZ In cancer of the bladder ordinarily there is such excruciating pain that it is unlike any other troubles One case I remember, a woman 65 years old, suffered in that way, the symptoms were a constant desire to micturate I examined her under an anæsthetic, dilating her urethra and introducing my finger, and found the entire posterior wall of the bladder covered by a growth which bled very freely on being touched The neighborhood of the entrance of the uterus was also involved, the rectum and uterus not involved The absence of pain in this case is striking In many forms of malignant growth pain is not a prominent symptom I imagine that epitheliomata are least painful of new growths I have a specimen of a man whose entire face and eye and a portion of the base of the skull and brain were substituted by epitheliomatous growth, but in a year that I treated him, he never took a grain of morphine

DR A H OHMANN-DUMESNIL presented a case of

LUPUS ERYTHEMATOSUS OF THE HAND AND ARM

It is the forty-fifth case on record In Germany, lupus erythematosus of the face is often seen, but the involvement of the hand and arm is comparatively rare, and in this country this makes about seventeen cases This boy is in his sixth year He came to me a little over a year ago, I recommended the application of lactic acid, and, subsequently, pyrogallic acid and soft soap, and it acted well for six months At first he had all the fingers involved, and the back of the arm At present it has a healthy appearance, which is due to the application of camphophenique and olive oil Commencing in the sweat glands, it extends to the upper layers of the skin It has a general erythematous character, but has nothing to do with lupus It is sometimes accompanied by pain, at present there is no pain When it first came it was covered with yellowish crusts, which consisted of coagulated blood When it heals it leaves a thin flexible scar, and there are little points, the remains of the glands Recent investigations have shown that it is due to a micrococcus It does not attack the papillary layer at all, that accounts for the thin skin Out of forty five cases the forearm was involved in only one case The average duration is six and one half years The section which I have under the microscope is made from an old preparation, which is a superficial part.

DR F R FRY exhibited a patient showing

THE RESULT OF AN EXCISION OF THE WRIST JOINT.

I first saw the patient in January, his wrist was then swollen and painful The physician who preceded me used vesicants, so that the appearance of the skin was deceiving I soon felt that there was suppuration and lanced it and found a free opening into the joint, made a counter opening, satisfied myself that there was dead bone Later, I made a still freer incision and scraped out the dead bone, put it in plaster The process continued and I had Dr Hodgen see the patient with me He agreed with me that excision was the thing to do and did the operation

DR HODGEN The operation was the ordinary one, through a single opening on the dorsal aspect. radial side, with this exception that it was only partial It is advised in these cases to make a complete excision, in this case I removed all of the first row and part of the trapezium, and also about 1½ inches of the ulna and radius At the close of operation the parts could not be brought together by about one inch, but subsequently, the inflammatory products being absorbed, this could be done, and I think that motion of the wrist is pretty good I hoped to have present an elbow that I excised about a year ago The boy suffered from tubercular ostitis, I removed 1½ inches of the ulna, one inch of the radius and one inch of the humerus There was nothing but a shell of bone The boy now has some flexion and extension, and it is a useful arm In regard to the wrist I removed all of the tissues that I thought there was any danger from

DR FRY I believe that trouble originated from traumatism, and yet it is difficult to explain the traumatism While in bed, the patient's room mate rolled on his arm, and he awoke with the pain The next day he worked hard with the hammer, and by night his wrist was practically helpless Its following so nearly upon this traumatism, and there having been nothing the matter with it before, leads me to believe that the traumatism was the cause of the trouble Prior to the operation the patient was in a very run down condition, but within a few weeks he began to gain and is now better than for several years

DR LUTZ I don't know of any joint more liable to sprain, next to the ankle, than the wrist Anything that will produce laceration of the connective tissue in the neighborhood of the joint will produce a sprain Sometimes the most trivial causes brings about inflammation about a joint, and I dare say that the doctor is correct, but he doesn't lay enough

stress on that peculiar general condition which fed and kept up the results of the traumatism A man run down in health sustains an injury, and there is an inflammation of the parts involved, another man sustains an injury of the same magnitude, and he being in good health, nothing results, which suggests the advisability of immobilizing the joint and the futility of rubbing on things I have made it a rule that when I can put the part at rest, I do it I don't see how any general condition could be made the cause of the inflammation about the wrist in this case I am in favor of the local theory They start from the local trouble and are fed by the general condition The hammering augmented it probably

Dr J K Bauduy, Jr, reported

THREE CASES OF DIPHTHERIA, ILLUSTRATING THE USE OF PAPAYOTIN

I found the first case, a daughter, with temperature of 103°, a rapid pulse and the patient greatly depressed I found on the left tonsil, extending back to the pharynx, an appearance which I said was suspicious, in the morning it was a marked case of diphtheria, the membrane extending onto the velum palati and uvula. I ordered papayotin to be applied As I am talking to a congress of medical men I will not dilate on the constitutional treatment, I think it ought to keep pace with the local treatment, however The next day two other children of the same family were affected, but as there was no more papayotin in the city, I had to treat them differently, and applied iron and glycerine In the first case I used a 5 per cent solution of papayotin, but now I take the powder and make a concentrated solution and apply every half hour, and in about twenty-four hours the membrane is about stripped off The fever at once dropped in the case spoken of, and remained that way, and I didn't use papayotin for twenty four hours I telegraphed to New York and got some more of the drug and began on the other cases Temperature, 105° in one, with great debility, membrane about the same As soon as I made applications to these cases the fever dropped, and the constitutional symptoms were less marked It is claimed for the drug that it is a germicide, and I account for its good effects from its germicidal properties, removing the influence of septicæmia by the absorption of that poisonous membrane The cases are all convalescent except one who has paralysis of the velum palati, but is otherwise doing well In the local treatment, papayotin is particularly useful, because it is not an escharotic to the normal membrane, merely eating the false membrane It acts better when prepared fresh each time *pro re nata* It acts as pepsin, and on that account has been recommended in indigestion and gastric derangements I generally add a little lactic acid to it It is valuable in preventing extension of this membrane, as extension kills the patient in a vast number of cases I put a piece of membrane in a concentrated solution of papayotin, and in about two hours it was dissolved entirely Whether it was a complete solution of the membrane, I don't know, as it was not given to a microscopist

Stated Meeting, October 15, 1887

The President in the Chair

Dr Edward Borck reported a case of

EXCISION OF THE ULNA

July 24, 1887, I first saw a man who had got caught in some machinery, which tore off all the muscles of the extensor side, laying bare the radius The pronator brevis was also torn in two, I was at a loss what to do The man would not listen to amputation No large blood vessels or nerves being injured, I removed all the superfluous muscles and let it stay till morning He had a powerful constitution, and we determined to try to save the arm The third day the pulse and temperature rose some for a day or two, then it sank down after a dose of Epsom salts, and the pulse varied from 82 to 83 for four weeks One morning about the end of August, he told me he had a chill during the night, then fever, and fearful suppuration set in, the elbow joint inflamed, and the case looked very bad The periosteum being destroyed, nature pushed out the ulna, leaving it almost bare I intended to save part of the bone, to saw it longitudinally, but the patient went from bad to worse, and I finally determined that the bone would have to be removed The tendons were all cut, and I took the tendon of the extensor minimi digiti and fastened it to the tendon of the communis digitorum, holding them together with a fine needle For a while he could move all the fingers except the little one, now he can move that too I removed the whole ulna, nature had already thrust it nearly out Already new bone had formed on the flexor side From that on, the patient did well, the wound healed kindly, except the formation of a few abscesses The power of repairing was so great that after opening one, the next day it would be healed I removed the bone September 11 For the first time he walked about to day I will present him here for your inspection I kept the arm at a right angle In the beginning, of course, I gave him nothing but a dose of Epsom salts, and a dose of morphine when he could not sleep When the fever and chills began, I put him on iodide of potassium, because it is the best antiseptic we have, I think—in large doses After the removal of the bone we gave him quinine Dressing consisted in the rinsing with Condy's fluid, and dressing with iodoform gauze In the beginning, nothing but warm salt water and antiseptic gauze

Dr T F Prewitt presented a case of

SARCOMA OF THE EAR

The case was that of a negro boy, aged 18 years He noticed about a year ago a little warty growth on the antitragus, and after about three weeks it was taken out He subsequently noticed that it had commenced to grow again in a month, it grew rapidly behind the ear He first came to the clinic June 13, and then had a projection on the front of the cartilage of the ear, about as large as the front end of a thumb, while the whole base of the ear was lifted up I diagnosed sarcoma, and as there was nothing else to do, I removed the whole ear It did

well, was healing kindly for a while, but later it commenced to grow behind the ear rapidly I concluded to attempt its removal a second time, and again commenced pretty well up and denuded bone, along the border of the superior maxilla, tied the external carotid artery—cutting the seventh pair of nerves in the first instance I removed the parotid gland, laying bare the internal carotid and vein That was three weeks ago Now it is granulating and there is no evidence of its reproduction so far

DR PREWITT then presented a case of

RESECTION OF A RIB FOR EMPYEMA

A boy 15 years old He had an attack of pneumonia beginning March 23 July 17, he first came to me, and I found an extensive effusion in the left chest, the heart pushed to the right, and respiration exceedingly difficult, he had fever and was looking badly I told the mother and himself that it would be necessary to open the chest, he was frightened and ran away, but he came back, and he permitted me to make an aspiration, when I drew off a pint of pus, and stopped then on account of dyspnœa The next day I aspirated and drew off three pints of pus, July 26, 1½ pints, again July 22 and 24, and a week afterwards I aspirated By that time it was evident that aspiration would do no good I had expected as much at first August 4, I opened the chest and resected the 5th rib, withdrawing an immense amount of pus, nearly two gallons I introduced a drainage tube, making also an opening lower down through which to run the tube Before opening the chest, there had begun to be a projection at the upper part anteriorly, about the third interspace, and looked as if it would ulcerate through in a short while The cavity was washed out and the boy improved The tube came out a few days ago

DR PREWITT also presented a case of

RESECTION OF ZYGOMA, OF UPPER JAW, REMOVAL OF PAROTID GLAND, AND LIGATION OF THE EXTERNAL CAROTID ARTERY FOR EPITHELIOMA OF THE FACE

One year ago an old man came to me, with an epitheliomatous ulcer on the side of the face, which I removed It healed kindly but he came back with the growth behind the ear as large as a hen's egg, firm, interfering with the movements of the jaw, and he was anxious to have something done I didn't give him an encouraging prognosis, but there was nothing else to do, and I attempted to remove it I cut down on it, found it necessary to resect part of the zygoma, and of the upper jaw, on account of the adhesions, and for the same reason removed the cartilage of the ear in front I had to remove also the parotid gland, tied the external carotid, and subsequently the internal maxillary on account of the recurrent flow The only things left in that region were the large blood vessels The old man bore the operation, and went home this morning

DR ROBERT BARCLAY Malignant disease of the ear is very rare, I have seen but three cases, one of sarcoma and two of carcinoma Another case, a tubercular syphilide, might have been taken for a carcinoma The sarcoma of the right concha was one inch long, ⅝ inch thick It began as a small blue spot extending directly outwards It was thought at first that it was an angia sarcoma, subsequent microscopic examination cleared the diagnosis There was nothing the matter with the ear except this growth, the glands were not involved It is the generally accepted opinion that sarcoma is very apt to be carried by the blood vessels, while carcinoma and syphilis are borne by the lymphatics If the poison in this case had been carried, we would hardly have thought that the glands would be involved, accepting this theory However, any inflammation about these is apt to cause enlargement of the glands This case I spoke of was operated upon by first removing with curved scissors, curetting and then the Paquelin cautery at a red heat It healed over, and several years afterwards there was no return of the growth After the removal of the auricle, it is a difficult matter to keep the canal from closing I have one case of atresia of the canal It was first a tubercular syphilide, then ulceration, and the thing closed with a very thick scar, except at one spot where it had been rather thin I operated, and had the usual difficulty in keeping it open I then introduced an elliptical cylinder, which has kept it open ever since The wound is cicatrized, and I hope to keep the tube there long enough to make the dilatation permanent

DR F J LUTZ Eight years ago I was subjected to severe criticism for resecting a rib, because it was supposed to be necessary I resected a portion of the ribs for pyo thorax, and I was, five years afterwards, fortunate enough to obtain a portion of the thorax *post mortem* What was then a comparatively new procedure, has since become established in surgery of the thorax in certain cases Its object in empyema is not simply an evacuation of the pus, there is another object, the approximation of the costal and pulmonic pleuræ, the obliteration of an abscess cavity hastened by diminution in the size of the thorax There is a marked difference in the two sides of the case, the left thorax is compressed Whilst in children, in whom all reparative processes are carried on rapidly, it may not be the *sine qua non*, it may not be necessary, yet in adults, many cases that are treated simply by incision and drainage tube are subsequently converted into chronic inflammatory troubles of the pleura and lung It has been suggested that a portion of several ribs be removed to facilitate the dropping in of the thorax The simple introduction of the tube does not in many cases accomplish the proper drainage of the cavity, unless it be placed in the most dependent portion, assuming the patient to be in the erect position, and a portion of the pus remains If laudable in the beginning, exposure will convert it into fœtid pus, and in spite of our efforts to wash it out the fever does not subside, septicæmia, and possibly pyemia, set up I believe it to be better surgery and safer, to proceed as Dr Prewitt did in his case

DR D V DEAN One method of treatment not mentioned, that of introducing a tube and having its other end in a fluid, keeping it constantly drained, might be better than resection

DR E H GREGORY I agree with Dr Prewitt and Dr Lutz I endorse everything that they have said There are comparatively few cases that require this graver procedure, but I certainly agree with Dr Lutz that there are certain cases in which it is required There is only one thing that I might take issue with Dr Lutz on, and that is regarding laudable pus I have been an advocate of that for many years, but there is a question in my mind whether there is any such thing

DR PREWITT So far as resection of the rib is concerned, I cannot see that it adds a great deal to the gravity of the operation It is easily done, you simply enlarge the opening into the chest, and the ribs are stretched apart, but as the contracting process goes on, these ribs approximate more closely than in health How could you retain any sort of drainage tube there without compression? Certainly, rubber will be compressed As to the glass tube, it seems to me that you don't want a solid tube sticking out into the cavity of the chest until the cavity is closed up If one could have a tube so arranged that the ends would turn up and lie against the wall it might do, but I didn't have such a tube Contraction of the chest is favored by resection, as Dr Lutz says, especially in the long standing cases of pyothorax where the lung cannot expand, and the space would be too great for the pleurae to come in apposition So we must provide for the further contraction by the removal of the bony wall I agree with Dr Lutz that, in adults, aspiration is truly worthless In regard to the antiseptic drainage which Dr Dean mentions, we might do it in hospitals, but it is not easy to do it in clinical practice, and it is out of the question in a case like this, he would never have staid on his back

DR. GLASGOW read a paper on

A NEW METHOD (CLOSED) OF TREATING ABSCESS CAVITIES

DR PREWITT I have been in the habit of injecting abscess cavities for several years with an emulsion of iodoform in glycerin I remember one case of a man who was shot in the chest I took out the ball *posterior to the scapula* Pus formed and suppuration ensued, and an opening was made in the axilla I was anxious to enlarge the opening of entrance, but he would never allow me to do it, finally, I injected the cavity with an emulsion of iodoform in glycerin He sprang up and seemed almost on the point of suffocation, and I really thought he was going to die, but reassured him It had gotten into the bronchial tubes, but from that time the cavity scarcely secreted any pus, and he rapidly recovered

Recently we had a woman, some months after parturition, with an abscess on the left side, just above the crest of the ilium, with an opening on the outer side of the ilium on the other side I was convinced that the openings connected, but was not able to demonstrate it, and I made an opening above the crest of the ilium and carried it over, made an opening below, evacuated pus and repeatedly injected glycerin emulsion, and in one of the washings water came out of the opening on the other side I don't know how the communication was made, but it seemed to pass across the pelvis Iodoform has certainly been of benefit to her, but not quite so promptly as Dr Glasgow mentions I have not had such good results, whether it is on account of the oil, I do not know As to its use in suppurating buboes, it would not be so successful, there you have a disintegrating gland that keeps up the suppuration, and often there is a chancroidal poison also

DR W JOHNSTON Those who have injected laudable pus, and no fever or unfavorable symptoms have been produced, will say that there is such a thing as laudable pus As regards injecting large abscesses, it is nothing more than applying nitrate of silver, etc, to an indolent sore, and the use of the oil would be to soothe the irritation

DR DEAN Beta naphthol, it is said, is poisonous, hydro naphthol is not so, it is claimed I have often used it

DR GLASGOW One point that was not touched on was that of dressing the abscess and waiting until it was healed before reopening it, as in fresh wounds By no other treatment can that be done, I believe

DR DEAN I think we will have to admit that the wound must be made aseptic before closing it, and that the solution that might remain would meet anything that might still exist there, supposing it not entirely aseptic

Antipyrin in Sea sickness—Action of Cocaine on the Digestive Tract—Diet in Gout—Potatoes as Food—Sulphobenzoate of Soda in Wound Dressing

Since the introduction of antipyrin into the therapeutics of this country by Professor Germain Sée, it has been freely applied to a variety of cases, particularly those in which pain was the predominating symptom In this it has almost completely supplanted cocaine, at least as an internal remedy For sea sickness it is now said to be unrivaled At a recent meeting of the Société de Biologie, Dr Dupuy stated that he had tried antipyrin in 11 cases of sea-sickness, and with complete success He administered it in doses of from 2 to 3 grams daily for two or three days before embarking, and this medication was to be continued during three days after departure Several theories were then enunciated as to the etiology of sea sickness, various remedies being vaunted according to the theories entertained by the different speakers According to Dr Dupuy's experience, sea sickness is a great deal more frequent and more severe in dyspeptic subjects, particularly in those who had dilatation of the stomach M Dastre said he had subjected animals to certain movements imitating as closely as possible those of pitching and rolling which one experiences on board a vessel at sea, and he found that under the influence of these

6 The objection arising from the existence of disreputable and incompetent pharmacists, applies with equal force to physicians, but has not prevented the organization of the American Medical Association

7 Such a Section would confer a social equality and standing on the pharmacists that would be healthy

8 It would throw them into professional contact with physicians pleasantly, and conferences could be had as to desirable points to be made, and the result would tend to prevent each from trenching on the other's domains

9 In the battle with disease, physicians, surgeons, dentists, specialists, pharmacists, and veterinarians, ought to move harmoniously forward against the enemy that means *war,* and *war* means *kill* or *be killed* Nothing is gained by derision and decrying opposition of one division against the other, which often result in defeat On the contrary, there is everything to be found by the mutual confidence, respect, and trust which such a Section would inspire and foster

10 The overture should come from the American Medical Association E CUTTER, M D

New York, November, 1887

MISCELLANEOUS.

OHIO STATE SANITARY ASSOCIATION —The fifth annual meeting of this organization will be held in Toledo, February 9 and 10, 1888 President, Prof E T Nelson, of Delavan, O , Secretary, R Harvey Reed, M D , Mansfield, O , from whom further information may be obtained

RUSH MEDICAL COLLEGE —In a recent number of THE JOURNAL we stated that Chas T Parkes, M D , of this city, previously Professor of Anatomy, had been appointed to the Chair of Surgery in the Rush Medical College, recently made vacant by the death of Prof Moses Gunn We are authorized to state now, that the Chair of Anatomy, made vacant by the transfer of Prof Parkes, has been filled by the appointment of Arthur D Bevan, M D , a member of the Faculty of the Medical Department of Wilamette University, Portland, Oregon, and a graduate of the Rush Medical College, class 1883

GREAT INTERNATIONAL COMPETITION OF SCIENCES AND INDUSTRY, BRUSSELS, 1888 —Eleventh Competition Medicine, Chirurgy, Hygiene, Balneology, Public Assistance Most of the Committees having asked that there should be no special regulations for their competition, it has been decided to refer to the *General Regulations* of the Great International Competition

The promoters of the Great International Competition have had a happy and fruitful idea In order to excite the emulation among the competitors, they have decided that the products should be grouped, according to their destination, so as to allow the immediate and complete study of a branch of industry, by the comparison of the similar products among the different nations Medicine is to our mind especially called to profit by this excellent innovation

And indeed, the medical sciences, as well as the arts and industries connected with them, have of late realized immense progress Such are those memorable and fruitful discoveries, made by the anatomo pathological works, by physiological experiments, by microscopical researches, and by microbiological studies Such are, besides, those remarkable ameliorations of chirurgy that allow the operator to work on all the organs of the body, even on those that by their position or their contexture, seemed condemned to remain eternally inaccessible to the hand of man

Such are, besides, the experiments of the laboratories and those scientific observations that have been the point of departure of those numerous works of hygiene the efficacy of which has shown itself by an increase of human longevity, in spite of the unfavorable conditions of modern life Such are also the therapeutic applications of the marvellous discoveries of physical sciences, thanks to which the doctor can utilize the greater part of natural agencies

The Great International Competition of 1888 offers a unique opportunity to make known to the public, that ignores it too often, that medicine has not remained stationary in the middle of the unceasing march of all branches of human activity We come to solicit your adhesion and cooperation in this generous enterprise, that will allow you to put in relief the part you have taken in these works

We submit to you the programme of the desiderata that the organizing committee of Class No 11 has decided to submit to the Competition, as well as the adopted classification for the medical compartment of the Exhibition

STAS, *President of Committee 11*
LENTZ, DR MOELLER, } *Secretaries of Committee 11*

General Classification —Subdivision 11*a* Medicine Subdivision 11*b* Chirurgy Subdivision 11*c* Public and private hygiene Subdivision 11*d* Balneology and therapeutic applications of physical agencies, aeropathy, electrotherapy, hydrotherapy, gymnastics, massage, climato therapy Subdivision 11*e* Public assistance

Officers of Committee No 11 —President, Mr Stas, Vice President of the Superior Council of Hygiene, at Brussels, Vice Presidents, Dr Crocq, Senator, and titular member of the Royal Academy of Belgium, at Brussels, and M Domis de Semerpont, General Secretary of the Ministry of Justice, at Brussels, Secretaries, M Lentz, General Director in the Ministry of Justice, at Brussels, and Dr Moeller, corresponding member of the Royal Medical Academy, at Brussels

N B —The persons who wish to obtain a complete collection of the desiderata formulated by the fifty six committees, can obtain them by applying to the Executive Committee, No 22 Rue des Palais, Brussels

CYSTITIS IN THE FEMALE

Contributed to the Section on Obstetrics and Gynecology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY HENRY O MARCY, A M, M D, LL D,

OF BOSTON, MASS

This paper is limited to the discussion of certain changes that are of common occurrence in the bladder of the female, and that are often so intractable to treatment as to warrant the query made some time since by one of my eminent surgical friends, "Did you ever know a permanent cure of chronic cystitis?"

The mucous membrane of the bladder is composed of epithelial cells, arranged in several layers The deeper cells are round, conical, or cylindrical, but they change towards the surface, until the superficial layer is composed of flat, laminated cells, which may be always seen in normal urine Mucous glands, simple and aggregated, lined with cylindrical epithelium, are found at the neck of the bladder and towards the fundus This epithelial lining of the bladder is continuous into the urethra, and contains there numerous large glands, glands of Lithré They are often 1 millimetre or more in diameter and from 2 to 5 millimetres in length They secrete mucus This delicate arrangement of epithelium plays a more important part than is usually ascribed to it, in protecting the highly vascular tissues beneath from injury arising from contact with the urine, an organic fluid so highly complex that, under certain conditions, it easily undergoes decomposition and becomes exceedingly irritating The mucus, secreted by the glands at the base of the bladder and of the urethra, serves a valuable protective purpose, but we shall see later that they may themselves become the seat of most important pathological changes which are generally overlooked In certain pathological conditions of the bladder, these glands may be easily distinguished by the unaided eye, as small pearly vesicles, filled with a transparent, turbid, or mucopurulent secretion The vascularization of the mucous coat is then greatly increased, and the increased nutrition causes a proliferation of epithelial cells of such a rapid growth that they widely depart from an even layering of a protective character, and not seldom appear as papillæ more or less prominent The muscular fibres become greatly increased by overactivity to expel the irritating contents of the organ The development of this irregular network of muscular fibres changes the symmetry of the bladder, the mucous membrane is thrown into crypts and folds from which the urine cannot be easily expelled, and thus, from step to step, the changes in this important organ may be traced, until a pathological factorage is developed inimical to life *Pari passu* the kidney, surgical kidney so called, often, perhaps generally, becomes affected, and a chronic nephritis closes at long range what at first seemed a simple affection

There can be no doubt that the more marked structural changes which are so often met with in the bladder not only in large measure incapacitate it for the fulfilment of its normal function, but also are beyond the remedy of our art The surgical treatment of rest, applied to this viscus by the artificial vesico vaginal fistula as devised by the late Dr Sims and still to a certain degree popular, may have a narrow range of usefulness, but to condemn a patient deliberately to complete incontinence of urine for a space of six months or longer is, for the time at least, a doubtful exchange of suffering, and the secondary closure of the fistula, except in the hands of a few experts, is an operation of doubtful outcome I cannot help thinking the primal causes of cystitis are in great measure overlooked Normal urine is acid and free from ferment It is a familiar experiment, and often a satisfactory test of condition, to pass the urine directly into an aseptic flask and stop with sterilized cotton If normal, it will undergo no change so long as it remains thus protected from atmospheric germs Thus it is with the urine in the healthy bladder, and even after the introduction of septic material into the bladder, often it will fail to germinate If it grows, the cystitis resulting, as a rule, passes off in a few days as an acute attack and the patient is again well The fortunate outcome results because the ferment is placed under conditions unfavorable to growth The bladder walls are intact with its unbroken pavement of epithelium, and the healthy urine furnishes little food for bacterial development

The germ bearing catheter, however, is rarely introduced under conditions so favorable Let the bladder be over distended and the protective layers of epithelium become disturbed or broken, and the vascularization and nutrition of the organ changed Again, in the familiar instance of the over distended bladder in parturition, where injury has been caused by uterine contractions and the vascularity normally greatly increased Now introduce the catheter, ven-

erable in the service of a score of cases of cystitis and never properly cleansed, or a clean catheter with all the becoming delicacy of our early teaching, "never to expose a woman," smeared after a few misdirected efforts with septic vaginal secretions, and note results

The soil of our new field is now well prepared for the sowing, and the harvest is sure Although it does not possess the danger of a septic uterus, the result is none the less certain The bladder, under these conditions, proves an excellent culture chamber, and the bacteriological ferment grows with marvellous reproductive power The lymphoid cells of low vitalization are easily destroyed, the epithelium and albuminates are readily assimilated, the urine is no longer acid, chemical changes result in new and irritating compounds, and these mischief makers, although so long overlooked because of their diminutive size, are potent to cause irreparable damage They are destroyed with difficulty, since the contractions of the bladder in the effort to expel its irritating contents only press the ferment into each infraction of surface and the mucous glands become new centres of colonization, and it is easy to follow the secondary and marked changes so long painfully familiar to the profession

In 1881 I had the honor of contributing to this Association a paper upon the treatment of cystitis and, as the result of a long period of experimentation, I then presented a series of double rubber tubes for the injection and irrigation of the bladder These catheters are of various sizes, ranging from No 18 to 25 F, and the efferent tube is three times longer than the direct, and thus over-distension of the organ is prevented The double tube was of course no novelty, but they had never been made of *soft* rubber, and many months of experimentation elapsed before the perfection of the tubes As now made by Tiemann & Co, of New York, they leave little to be desired and are as perfect in finish as the best of soft catheters The exquisite finish of the surface and eyelet is secured by curing at high temperature in molds of very hard annealed glass

The relief sought is not a simple disinfection For reasons already referred to the cleansing of the bladder is attained with much difficulty and, on this account, the hot douche proves of the greatest service I have been for years in the habit, in chronic cases of cystitis, of directing the water to be used as hot as comfortable and to be continued for half an hour morning and evening The result is comparable with the hot water vaginal douche, not only to wash away the mucus and decomposing urine with ferments, but especially to lessen the vascularization of the bladder and aid in the reparation of the epithelial protective layers of cells A long series of experiments were undertaken to ascertain the antiseptics best suited to be used in the bladder, and the intolerance of germicides in the bladder is most remarkable Generally a 1 to 5,000 mercuric bichloride solution is followed by severe pain and tenesmus, often lasting for some hours A 1 to 10,000 solution has been used more often than the weaker solutions, and it is very effective in this strength, but not seldom have I been obliged to suspend its use entirely, or substitute a much weaker solution Only recently a case has been reported to me where a 1 to 80,000 could not be continued because of the pain The better way is to cleanse first the bladder with warm water, then use the antiseptic as strong as judged best After its retention for a few minutes allow it to escape, and follow immediately with the prolonged hot water douche By so doing, the good result of destruction of ferment is accomplished by the use of a comparatively strong solution, and the deleterious secondary result prevented by lessening the blood supply, nerve irritation, etc It is always well to remember that the water should be boiled water, cooled to the proper temperature In the city this is ever at hand in the water from the hot faucet, as this has always been carried to a high temperature before reaching the boiler

The bladder tolerates iodoform well, and the treatment is finished by injecting a few grains in suspension which is allowed to remain This soon settles to the base of the bladder and is not easily expelled It dissolves less readily in the bladder than in most parts of the body I examined recently a specimen of urine voided at will which contained a large amount of iodoform In reply to my inquiries I found the patient, a man, had for some time taken a teaspoonful of iodoform in suspension as an injection daily without inconvenience

The treatment outlined above is repeated night and morning, until the urine is free from bacteria, then daily for a period, and often twice or once a week until sure of cure The bladder tolerates hot water singularly well In a very troublesome case of cystitis in an old man with a greatly enlarged prostate, the injections were continued for a long time at hourly sittings The 4-quart rubber bag makes the most convenient receptacle for the water When properly adjusted the fluid flows in an unbroken stream into and out from the bladder with very little inconvenience, often with distinct comfort to the patient

In one case of vesical hæmorrhage, resisting all other measures, the patient in extreme danger from the loss of blood, I continued the flow of hot water through the bladder uninterruptedly for forty eight hours, followed by cure without any return of hæmorrhage

In earlier years, I often felt it necessary to dilate the urethra, as a measure also of much value in order to lessen the irritation and tenesmus It has been supposed that, in order to be of value, there must be a fissure in the neck of the bladder, and this method of treatment appears to have been based upon the remarkable results in fissure of the rectum after forcible dilatation It at least, in a measure, paralyzes for a time the muscular fibres which surround the entire urethra This gives an easy outflow to the urine with little pain or spasm for some days, and thus relieves the continued tension of the bladder I have certainly seen some remarkable cures follow this treatment There is no rule for guidance in the selection of cases, but it would appear unwise and ill chosen unless there was some organic lesion of

the urethra With the modern means of examination, there can be no reason and should be no excuse for not knowing the condition of the entire urethra Dilatation is not without some danger of ill result, hæmorrhage may be excessive and troublesome Paralysis and incontinence may follow even when care is exercised and the surgeon fully competent

One of our prominent modern authors[1] states "that the relation of cystitis to the formation of vesical calculus cannot be passed by without further notice That a certain degree of irritation, if not of inflammation, is a constant factor in stone production there can be but little doubt Let us observe what follows the excitation of inflammation of a moderate amount in the bladder, by the introduction into it of an extraneous substance A piece of bougie may thus become accidentally lodged, cystitis is produced, the urine is renderd alkaline and phosphates are thrown down in abundance and aggregated around the foreign body" Here, as with all authors, almost without exception, it is referred to the "irritation or inflammation" produced by the foreign body, as the cause of all the mischief, without a hint that the something beside the bougie, namely the bacterial ferment, was the real cause of rendering the urine alkaline and that, on this account, the subsequent chemical changes took place, resulting in phosphatic concretions

Dr Bigelow's lithopaxy has clearly taught the lesson, too little emphasized, that the "irritation or inflammation" resulting from an hour's operation within the bladder, itself seriously diseased, is less to be feared, if the organ is left *clean*, than many minor surgical operations done without aseptic conditions

In a variety of ways, the gonococcus of gonorrhœa may and actually does find its way into and reproduces in the bladder, giving rise to severe cystitis Here the common cause is the introduction of the bougie, or sound, either carrying with it the ferment already growing in the urethra, or introducing it into the bladder by a contaminated, unclean catheter Ferment thus introduced is by far the most common of all causes of cystitis The vagina is never free from actively growing organisms, and the one invariable rule of catheterization is an aseptic instrument, introduced into a surgically clean urethra As ordinarily used, an instrument for each patient means but little Let the catheter be constantly kept in a solution of mercuric bichloride, 1 to 1,000, and carefully cleansed with the same before its introduction

I have felt it a duty to enforce the above lesson, not because it presents any especial discovery or, at this date, real novelty in practice, but rather as the practical deduction of the normal evolution of the *rôle* of the ferments developing in this important organ, deductions based upon years of observation and a large experience in private and hospital practice, all the more important since, I am constrained to believe, care as above described is prevention, and measures so simple and effective in cure are yet the exception to the rule of treatment

AFTER-TREATMENT OF CATARACT EXTRACTION

Read in the Section on Ophthalmology, Otology and Laryngology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY W T MONTGOMERY, M D,
OF CHICAGO, ILL

Some of the gentlemen now present, will remember a brief discussion of the after treatment of cataract extraction and iridectomy, introduced before this Section one year ago, by Dr Chisolm, of Baltimore The doctor promised to give trial to the after treatment of extraction and iridectomy without the dark room, with more freedom and less bandaging, and report the result We all know how soon and how well he fulfilled his promise I stated in the discussion one year ago, that for six months previous, it had been my custom to permit cataract patients to leave their beds the third day after extraction, and the fourth or fifth day to substitute the green shade or smoked glasses for the bandage, and with better results than when I had kept the patient in bed in a dark room for from one to three weeks I continued to treat my cataract patients as I then indicated, until Dr Chisolm's first report appeared After reading that report, the question as to whether or not it is necessary to put the patient to bed at all after cataract extraction, suggested itself to my mind As I could see no urgent reason why they should be, I determined to try a more liberal treatment even than that outlined by Dr Chisolm

Since July 22, of last year, I have made twenty extractions, twelve infirmary and eight private cases, and with two exceptions all have been treated as follows Von Graefe's linear operation under cocaine was made in every case Only the eye operated on was bandaged, and the patient was put in a quiet, moderately lighted room and permitted to sit in a chair, walk about the room or lie on his bed as he felt inclined The only precautions to the patient was to avoid violent exertion or sudden jar The dressing was not disturbed until the third day unless the patient complained of pain or the bandage became displaced The third day the dressings were changed, the eye bathed, and a 1 per cent solution of atropia sulph instilled between the lids In all but three of the cases the bandage was left off the fourth or fifth day, and the shade or colored glasses substituted, and the patient permitted to go to his meals and walk about the house The exceptions were two cases in which the vitreous presented, and it was necessary to introduce the spoon to remove the lens These patients were put to bed and the eyes kept bandaged until the reaction, which was severe in each case, had subsided A third case in which the bandage was necessary for a longer time, was one in which there was extensive choroidal degeneration, and although the corneal wound healed readily, repeated hæmorrhages into the eye occurred The patient in whom this occurred had cataract in both eyes, and extensive posterior staphyloma, with barely perception of light in either I made extraction on both eyes at different times against my better judgment, but at the earnest

solicitation of the patient, and hoping to give him a little more light His vision was not improved, but it was not the fault of the method of treatment

In none of the twenty cases was there any corneal infiltration or delay in healing of the corneal wound In only one case, except those already referred to, was there iritis In this case one eye had been operated on four or five years before by the downward incision, and consequently I made the cut downward on the second eye The wound would open occasionally and the aqueous gush out The third day the patient began to have iritis, which became quite severe and delayed recovery to some extent

Two of the private patients visited my office the eighth day after operation, wearing only smoked glasses I think any of the uncomplicated cases could have done so had it been necessary At the end of the first week there was still slight vascularity of the cornea at the seat of the wound, but the eye was free from irritation and bore the light well

As to the final result I am unable to give it definitely in every case, but feel safe in saying that the vision obtained was up to the average in a series of twenty cases

It is not my purpose in presenting this brief report, to try to prove that I have obtained better results by this method of treatment than can be obtained by the old I wish simply to offer this for what it is worth towards establishing what I believe to be is a fact, and that is that this line of treatment is entirely safe I mean in uncomplicated cases without accident during operation I did not use it in the two cases with loss of vitreous, nor would I use it again in a patient on whom I had made the downward incision

I think it is generally conceded, that we cannot prevent more or less rolling or motion of the globe of the eye, no matter in what position we place the patient, what kind of a bandage we use, or whether we close one or both eyes I don't believe the motion of the globe does any harm if the lids are kept closed A very gentle pressure or force is sufficient to keep the lids of one eye closed, even when the other eye is allowed to remain open The dressing that will most effectually accomplish this, and with the least discomfort to the patient, is the most desirable In the first half dozen cases I used the isinglass plaster as recommended by Drs Michel and Chisolm The weather being very warm and the patients sweating more or less, I had difficulty in getting the plaster to adhere, and when it did adhere it soon became dry and uncomfortable to the patient I abandoned this for the gauze roller bandage, using enough absorbent cotton to even up the orbital depression and make gentle pressure upon the lid This bandage is cool and quite comfortable, and moistened before it is applied retains its position the best of any dressing I have tried

We all know how trying to the comfort and health of the patient the old-after treatment is I have more than once been more concerned about the general condition of my patient after extraction, than about the amount of vision he was going to have An intelligent lady, on whom I recently made extraction, had had extraction made on one eye four years ago When she came to make final arrangements for the operation on the second eye, she said, "I don't mind the operation a bit, but I can't bear the idea of lying on my back in a dark room for nine days as I did before " "Why!" she said, "they would not allow me to raise my head or chew anything, but kept me lying on my back until I thought I would die " The most marked advantages of this treatment over the old are

First, less discomfort to the patient, second, much less danger to the general health of the patient; third, a more rapid recovery from the operation

Needle operation and iridectomy have been treated in the same manner, except that the bandage was removed entirely the third day in most cases.

THERAPEUTICS OF PULMONARY PHTHISIS

Read before the Monmouth Co , N J , Medical Society

BY GEORGE T WELCH, M D ,

OF KEYPORT, N J

It is excellent judgment, before debating the therapeutics of a disease, to inquire into its natural history and ascertain whether there are any instances of its self-limitation and any of its cure by the use of drugs It is so much the habit of medical men, like hired archers, to rush to the rescue of every man assailed by a disease as if he were having his jugular vein drained by a tiger that, together with the promiscuous shower from slings and bows, and thrusts of the short sword, it is a cause for congratulation if the man escapes instead of his enemy And it is altogether a matter of conjecture whether his individual prowess might have succeeded in ridding him of the object of attack So much is this the case that I dare aver we know very little of the real natural history of any but the simpler forms of disease—the symptoms are so overlaid by the physiological effect of drugs But that pulmonary phthisis is sometimes self limited, and sometimes curable in a sense, would seem to be proven by a rare case now and then, though a vast majority of the affected die, and, as is shown by the Board of Health Reports for N J , a little more than 23 per cent of all deaths, among adults, in this State, is caused by this disease

And yet some escape Lænnec and Louis have demonstrated it in the wide range of statistics which they have marshalled to the fore, and it may be that every large neighborhood can furnish one instance That this could be so before more enlightened methods of practice were followed by the advanced members of the profession within the last five decades, speaks volumes for the recuperative energy of that silent force which underlies all the manifestations of life Dr Griffith mirrored the practice in this State, at the end of the last century, in his "Dissertation on Pulmonary Consumption," read before the New Jersey Medical Society, May 3, 1791 It was "small blood lettings frequently repeated, gentle emetics of ipecacuana, out door exercise, expressed oils, mucilages, emollient vegetables, opiates, ripe fruits, low diet, laxatives, blisters, setons, issues and frictions "

When the patient, nothing loath, let us hope, had arrived by such stages, hard by the iron doors that fence immortality, and things were now desperate, the good doctor acknowledges he can not be saved, but if he could it must be done by smaller bloodlettings and a lower diet!

In the year 1817, Dr M Freeman reports four cases cured out of seven by the following laudable means "I push," says he, "the lancet and digitalis cautiously but freely, that is, I *try to reduce* the pulse below 65 or 70 for the first five or six days, after which I endeavor to reduce it lower and maintain the depression for two or three weeks, in spite of prostration and nausea At the same time recommend milk and vegetable diet, together with a perfect tranquility of mind and a horizontal state of the body, when the pains are wandering about the thorax" Then he advises blisters, stimulating plasters, and a seton All this for the first stage of the disease For the second step—digitalis, a nourishing diet, which must not excite irritation The patient upon any unruly manifestation of the disease must now take oxide of mercury and be kept salivated for two or three months, and must be *dosed* with a mixture containing "four grains of alkali and a fourth of tartar antimony, given according to the age and strength of the invalid"

By this means Dr Freeman says that he cured J Devoll, Mrs Crowell, Mrs Latourett and Mrs Gage, all within a year, "now well and enjoying better health than they have had for twenty years past Two of them were under ptyaloid symptoms for sixty days before the latter disease had the ascendancy of the former they took more than 200 grains, and a constant application of the mercurial ointment" This atrocious practitioner ends by saying, "even in an advanced and fatal stage, if the stomach will bear these remedies, they will mitigate their distressing symptoms and thereby tend to smooth the declining passages and quiet the hour of death" Which is to say, if St Lawrence had been dosed with calomel, antimony, digitalis, and been blistered, bled and tickled under his midriff with a seton needle, as he lay slowly consuming on the devilish gridiron of the Inquisition, he might have gone almost voluptuously to his death!

The practice did not change much for the next thirty years, though I find in the recorded Transactions of the State Society before 1850, occasional allusions to the decrease of phthisis as though it was at length succumbing to heroic measures, but as there was no basis in statistics for such assertions they must be amiably passed by

About the year 1841, cod liver oil became generally known, and was extravagantly lauded as a curative in this disease Dr Geo B Wood, (in the 4th edition of his work on the Practice of Medicine, 1855,) speaks of it as being of inestimable value, says he gives it in all cases of the disease and at all stages, and declares its universal use has reduced the death rate from 1 in about 6 76 from all cases before 1850, to 1 in 8 22 While Condie with some enthusiasm pitted the reduced mortality of 1850–51 against the twenty-three preceding years, as being due to cod liver oil, though in the next two years the ratio increased Late in his life Condie saw fit to modify his views as to the curability of pulmonary phthisis, and in a paper on "Spurious Consumption," pointed out the errors in diagnosis which frequently attributed a cure to the former disease when the latter was alone benefited

Cod liver oil gradually fell into some disrepute, as it was found that it was unfitted to several phases and stages of pulmonary tuberculosis, and at the best only delayed the fatal issue, until now it is the average opinion that it does not exert any influence upon the structural elements of the disease, but in all likelihood receives the credit of cure in those cases where the organic trouble is limited, or is benefited by such measures as have restored other patients without it In my experience it has never answered the hope entertained for it, and I have within the last six years completely abandoned its use in the disease under consideration The digestive organs, as is well known, speedily succumb in this affection and when dosed with the oil produce, besides the dyspepsia, a loathing for food which is justly a subject of great concern, and not to be tolerated Even the emulsions produce, in my experience, the same unhappy effects

And because of this weakness of the digestive apparatus I look upon over-feeding as a means of cure, as being barbarous and unscientific I have not, however, condemned it without trial, but, though a certain tolerance for a time can be established, yet in a few weeks, or months at the best, it can be carried no further, and the fatal end is then provoked instead of banished Emaciation progresses in well defined cases, even when a moderate appetite is present, showing assimilation is not perfect, and then to crowd the function of digestion, though assisting with artificial means, is to offer an overplus of nutritious elements to tissues that can not accept the bounty

I recall several cases that for a time gave the most flattering promise under the use of maltines, alcoholics, hypophosphites, arsenic and tonics, but the medicines lost caste, they no longer held up the flagging energies, and I have often in bitterness of soul execrated the means that kept the dying on the rack For better it seemed, as I recalled the last months or weeks of sickening, sinking disease, that one could give euthanasia than with such reprieves hold the poor wretch in sight of his open grave so long

But I recall one case of a gentleman who had long been subjected to the extortions and doses of a physician who was also proprietor of a drug store When he came under my care I prescribed maltine, syr hypophos co (Fellows') and whiskey—nothing more He had a racking cough, tuberculous deposits in one lung, night sweats, palpitation and loss of appetite He was sent into a more genial climate for the winter, and the medicines were persisted in faithfully, in what seemed months of hopeless disease The cough gradually grew less and finally ceased, the pain stopped, the heart regained its wonted tone, the appetite returned, flesh was gained—in a word the man was restored to his old vigor, and for four years has fol-

lowed his occupation as a market-gardener without a return of the disease For awhile there was cavernous breathing, which in time became less and less noticeable

W N, a young man 20 years of age, who had cough, profuse sweating, loss of appetite, great debility, with signs of tuberculous deposits in the apex of each lung, and who was intractable as to the use of medicines, I sent to Florida, where, in a dry district, he spent his days in the open air for several months, riding mostly, driving, and as to drugs taking nothing but maltine He returned in May without a trace of his former disorder, and continued well for two years and a half, when a severe bronchitis was contracted, from which he was slow in recovering but without awakening the old disease

A W, æt 21, had cough, slight hæmorrhages, pain in the chest, pneumonic stitches, dyspnœa, evidences of the first stage of phthisis He was sent to Colorado, and from there, by the advice of Dr Denison, he went to New Mexico, investing in a sheep ranch and roughing it on the plains for a year or two Recovering, without drugs, from all his unfavorable symptoms, he went back to Denver, where he has now carried on a successful business, involving a great tax of energy, having several men under his employ, for the past four years, without any return of the disease

I have sent other patients to higher altitudes, on sea-voyages, to Florida, and have used whatever means appropriate climatology presented, but these three cases are the only ones I can present of arrested disease I am glad I can not remember how many others I have conscientiously treated in the light of all the recent authorities, without avail

But to these three might be added another as coming under my notice, though not at the time he was consumptive Mr H W J, a banker, who at the time I first knew him, twelve years ago, had but just recovered from an abscess in his right lung He had passed through all the symptoms of grave tubercular disease, but after this abscess had discharged itself, his health recuperated, and there were no further manifestations of the disease I have examined his chest on many occasions It is sunken on the affected side Twelve years ago there was cavernous respiration, the voice was hollow, and there were yet flying pains about the thorax As years went by cicatrization proceeded until now there is only a faint vesicular murmur to be heard, and though Mr J has had two attacks of bronchitis since, there have been no further symptoms of pulmonary disease

Dr Wm A Newall, late Governor of Washington Territory and long a practitioner in this county, has related before this Society his spontaneous recovery from pulmonary phthisis, under the influence of horse-back riding through the pine forests of this State, during some years of his early life

Dr I S Long, of Freehold, has given me the details of the recovery of a patient after profuse hæmorrhages, expectoration, sweating, and almost moribund condition, when the forlorn hope of drugs had been called off So, you will perceive it is in the natural history of this disease that patients sometimes recover without drugs, and in spite of drugs But the cases are few, and the desert is covered with the mournful drift of whole caravans between

There are a hundred so-called remedies I have not named, as oxygen, pneumatic differentiation, and others, but by a singular coincidence they that have an apparatus to sell are loudest in commendation of its process and results Bergeon's method is the latest craze, and from observations in its use during a few days, or at most weeks, it did seem to hold out some promise, while lacking the test of time which has dispelled so many mirages But it has already fallen into disrepute So, while it is well to resort soberly to all that is reasonable and scientific, I can not too strongly reprobate the extravagant use of drugs, as I have seen in many cases in which various and diverse medicines were used for every important symptom because the only known recoveries from this disease have been those in which the tuberculous deposit was limited, and were such as change to suitable climate and hygienic measures brought the highest result and would have been in all likelihood sufficient without the interference of so called remedies

---

VAGINAL HYSTERECTOMY REPORT OF FOUR CASES

BY J H ETHERIDGE, A M, M D (RUSH),

PROFESSOR OF MATERIA MEDICA, RUSH MEDICAL COLLEGE GYNECOLOGIST TO THE PRESBYTERIAN HOSPITAL AND TO THE CENTRAL FREE DISPENSARY

The three cases reported herein were operated on at the Presbyterian Hospital I can never convey an adequate idea of the relief to the operator offered by the method of hæmostasis by forcipressure on the broad ligaments over that of ligatures I think no one can fully appreciate the untold superiority of the former method over the latter till he has had experience in the performance of that operation under both methods

Case 1—Mrs S, æt 47, mother of nine children, always well, presented herself February 1, 1887, with epithelioma of the cervix uteri It did not involve the vault of the vagina The broad ligaments did not seem to be thickened Mobility of the uterus was complete After preparatory treatment with a daily laxative and diuretic for a week, the operation was performed on February 8, 1887

The cervix was easily drawn down to the vulvar orifice and, with scissors, its vaginal attachment was divided Strong adhesions to the bladder and rectum were found, and in consequence thereof, the rectum was opened in one place and the bladder in two places in the process of freeing the uterus from these two organs After the two broad ligaments were sufficiently isolated and the fundus was turned backwards and brought down, the left broad ligament was first penetrated and divided into two sections with heavy ligatures, and tied as securely as hands could tie them It was then severed as closely to the corpus uteri as possible, and the whole organ came out of the vagina Treating the right broad ligament similarly was a much easier matter, because the uterus was down and out of the way This attach-

ment was at once severed and the whole organ was then freed from the patient The ovaries were then removed The rent in the bowel was closed by continuous suture without difficulty The longer rent in the bladder was then closed by continuous suture, but it was done at a great disadvantage from its peculiar position, back of the symphysis and looking directly backwards To draw down the bladder and to so evert the edges of the rent as to apply the stitches was a delicate and difficult task The smaller rent, undiscovered at that time, was not closed Just as this sewing up was completed there was observed welling up into the shapeless excavation left after the removal of the uterus great quantities of arterial blood Which broad ligament it came from it was impossible to decide After a long time the bleeding vessel, which was in the right broad ligament, was secured, but not till after a ligament was pushed off of the left broad ligament All vessels were eventually secured, but not till a great quantity of blood had been lost The top of the vagina was closed from before backwards with continuous suture, the ligatures were brought down, iodoform gauze stuffed into the vagina and the patient put to bed

Reaction followed reluctantly She died from peritonitis and exhaustion in 45 hours, having passed 8 ounces and 1 drachm of urine in the meantime The autopsy revealed a small rent in the bladder, which was concluded to be the cause of the peritonitis

Case 2 —Mrs C , æt 36, laundress, tall, spare, nervous, sanguine temperament, presented herself February 10, 1887, with a small epithelioma in the cervix uteri The upper portion of the vaginal cervix was not invaded The choice between amputation of the cervix and hysterectomy was left to the patient after full explanation of the dangers and results of the two procedures She decided to have the latter operation, which was performed on February 25, 1887

The uterus was easily drawn down to the vulvar orifice and freed from its vaginal attachment with the scissors The bladder was uncommonly closely attached to the uterus, and before its complete separation was accomplished it was opened The opening into the Douglas cul de sac was easily effected and the fundus rocked backward through the sacral hollow, down and out through the vulva The broad ligaments were secured with silk ligatures and the uterus removed after its separation from them The ovaries were separately removed immediately afterwards In closing the vesical rent the left broad ligament shed its ligatures and bled profusely Hæmorrhage was soon checked The vagina was closed from before backwards, the ligatures were brought down into the vagina, and the latter organ was filled with iodoform gauze

The patient rallied well The temperature rose to 100° on the second and third days Thereafter nothing worthy of special mention occurred On the tenth day an elastic ligature attached to the patient's left thigh was tied to those protruding from the vagina, and in five days they began to come away and in 48 hours the last one was removed In 36 days she left the hospital

Case 3 —April 13, 1887 Mrs C , æt 49, widow, last confinement 28 years ago, she is still menstruating regularly every three weeks, flowing one week

Six months ago she began to have leucorrhœa and to lose occasional small amounts of blood She has excellent general health She is a good breakfaster, digests well and is a good excreter from the bowels, kidneys and skin She is well nourished, and presents a promising outcome for any surgical ordeal The only thing that one could wish different in her general aspect is a too rapidly acting heart It beats over 90 times per minute and the arterial impulse is persistent She has often seen lateritious deposits in her renal secretion

Examination reveals an epitheliomatous degeneration of the cervix, with about ¼ inch of uninvaded tissue of the cervix between the cancer and the vaginal vault The uterus was about 4 inches deep and it bled freely upon withdrawing the sound The fundus was large and was easily felt through the abdominal wall The uterus was freely movable, indicating the non implication of the lymphatics in the broad ligament The absence of invasion of the vaginal wall and of the circumuterine tissues led to the recommending an operation for the removal of the entire uterus

From April 19 till May 5, the date of the operation, she took cascara daily, and digitalis and acetate of potash The condition of the excretions seemed as nearly perfect as possible prepatory to an operation The patient slept in the hospital the night before the operation, and took the customary general antiseptic bath and had administered several vaginal bichloride douches

Operation —The cervix was drawn into the vulva with two large, lock vulsella forceps while the vaginal attachment to the cervix was divided with the scissors Gradually and patiently the circumcervical tissues and the attachments of the bladder and rectum were crowded away with the finger nail till the Douglas cul de sac could be opened Then it was found quite impossible to reach the top of the fundus with the fingers The cul de sac of peritoneum between the bladder and the uterus was then opened, with hope of being able to retroflex the uterus by means of the fingers placed before and behind the uterus This manœuvre was found likewise to be an impossibility After repeated vain attempts to reach the top of the fundus with the fingers, that method was abandoned Trial of very deep suprapubic pressure to thrust the fundus back toward the sacral hollow, and at the same time of grasping and pulling down the fundus with a small vulsellum forceps thrust through the Douglas cul de sac, at last succeeded, after three or four tearings out of the forceps, in getting the top of the uterus out into the world

Snap forceps were then placed on the broad ligaments and the latter divided The subsequent dressing consisted in tucking a thin layer of iodoform gauze into the vagina, care being taken to avoid separating the top of the vaginal walls The danger of this separation must be patent to any observer Ribollet attributes the death of one of his patients to crowding too much gauze into the upper vagina

No stitches were used to close the upper end of the vagina Its borders were permitted to collapse and to close in any position that they chanced to occupy The fear that the bowels and omentum might seek an outlet through the vaginal tract is wholly groundless One ligature was used for a vaginal artery No attention was paid to it in the final dressing The ovaries were both removed after the uterus was finally separated from its attachments

The patient reacted well from the shock of the operation, which consumed seventy-five minutes Her daily progress was so uniformly satisfactory that any detailed descriptive statement of it would be monotony itself The pulse ranged from 90 to 120 beats per minute, it was 98 when she left the hospital The temperature reached 100° one *morning* only, and on five evenings, from third to the seventh days inclusive

The amount of urine passed daily during the first fourteen days after the operation is indicated by ounces in the following figures 19, 19½, 25, 23, 26, 24, 23½, 25, 30, 31½, 34, 40, 35 and 26½

The forceps, one pair on each ligamentum latum, were removed at the end of 48 hours Although anyone knows that 48 hours of obliteration of the lumen of an artery must necessarily destroy its patency, yet the writer was filled with misgivings when the forceps were very carefully unsnapped and as carefully removed as gentleness itself could supervise The folds and creases of the vagina, as far up into the shapeless excavation as vision could peer upon an exaggerated separation of the vulva with the fingers, were watched with an intensity of eagerness and anxiety, for their being inundated with the hot scarlet blood that so easily comes from the ovarian and uterine arteries, that can be appreciated only by him who has experienced those emotions No bleeding followed the removal of pressure from the uterine ligaments The vagina was not again filled with gauze Iodoform was blown into this cavern as far as was possible daily

It was impossible to state definitely the amount of drainage that escaped Perhaps 3 tablespoonfuls daily for the first two days would cover it, afterwards the amount could not have been more than 1 tablespoonful on the third and fourth days each After the fourth day none escaped to mention

Case 4 came to me in Oct, 1887, for an incoercible hæmorrhage from a small fibroid tumor in the posterior uterine wall The patient, a woman 47 years of age, has borne eleven children, and has been having hæmorrhage for eleven years Everything in the way of medicine has been tried, the uterus has been curetted upon two different occasions, and she came to me supposing the ovaries must be taken out I explained to her that I had had two cases of removal of the ovaries for hæmorrhage, but that the operation had not cured the hæmorrhage I also explained to her the danger of removal of the uterus and she consented to the operation The steps were simplicity itself, being a repetition of what I have given The cervix was easily drawn down to the vulvar orifice and the cervical attachments freed at once as speedily as possible An incision was made in the cul de-sac of Douglas and I was able with a knife to divide the tissues without any trouble I kept as close to the uterus as I could, and did not open the bladder When the two broad ligaments were all that supported the uterus they were secured with long snap forceps, and the broad ligament divided on the right and left sides Snap forceps were put on the neighboring deep vessels, that was all the hæmostatic means that was resorted to from beginning to end

The patient was put to bed about 3 o'clock, and about 6 I was telephoned that she was having a severe hæmorrhage Concluding that it was one of the arterial branches from the vagina, I hoped that ergot would stop the hæmorrhage When I reached the hospital I found that after the use of the rectal injection of ergot the hæmorrhage ceased The case ran along very well for 48 hours, afterwards the temperature was 99° for two or three days and then it ran up to 101° She was put upon the table and the wound exposed with a Sims speculum Up in each angle or cornu of the wound was a black gangrenous-looking mass about as big as my little finger, hanging down upon the vagina, which mass protruded from a little cavity filled with the débris of blood, which had probably been produced by the hæmorrhage on the day of the operation It had decomposed and was smelling very badly That mass was pulled out In the other side I was able to pass the forceps up a distance of about 1½ inch I removed all of the shreds and put the patient to bed The temperature at once went down to 98 2°, and since that time everything has progressed satisfactorily This is the twenty first day since the operation I saw the patient this afternoon, and she calls for solid food and is to sit up to morrow The following are some points of interest concerning this operation

1 *Indications for its Performance*—(a) Ten years ago, and indeed until quite recently, the chief indication for the performance of vaginal hysterectomy was malignant disease At present it is agreed by all operators that the earlier it is performed for cancer the greater are the chances for its non-recurrence This dread malady always returns sooner or later after amputation of the uterine cervix, and of course proves fatal, whereas, when the whole organ is removed, the patient is given the only hope of a permanent recovery Hysterectomy does not always prevent recurrence of the development of this neoplasm, yet it offers the best results Martin reports 8 cases of hysterectomy from cancer without relapse, varying from two and one-half to five years According to Sanger the average of survival after this operation is eleven months Olshausen reports cases after operation of relapse, once after eighteen months, twice after two years, and twice after three years

The most favorable conditions offered for hysterectomy are the non-involvement of the vagina, and complete mobility of the uterus, which shows the non-invasion of the *ligamenta lata* In other words, the earlier in the disease the operation can be performed the better are the promises of a radical cure Only too often does it occur that the disease

has advanced too far before the gynecologist is consulted

(b) *Procidentia uteri* is another condition for which this operation is performed Amplastic operations do not always restore the organ to its normal level Artificial vaginal stenosis to the extent of the non-admission of the little finger has failed ultimately to relieve the procidentia through gradual dilatation of the vaginal channel

(c) Fibrous bodies of the uterus which offer the point of departure for serious irregularities have constituted a cause for vaginal hysterectomy Of course reference is had to small tumors Heydenreich reports four cases of operation with four successes He[1] considers that at present it is impossible to pronounce upon the relative merits of vaginal hysterectomy and of castration for small fibrous bodies in the uterus Péan[2] recently reports a case of the same operation for multiple fibroids

(d) The hystero neuroses (inveterate dysmenorrhœa, neuralgia, convulsions, etc), for which oophorectomy is so often performed, Péan considers a justifiable cause for this surgical procedure His reasoning is, that these neuroses sustain an intimate relation to the uterus itself, consequently the uterus should be included along with the tubes and ovaries (Caldwell Paris Letter in *Chicago Med Jour and Examiner*, February, 1887)

As an illustration of the *furor operativus*, a recent article from the pen of a Cologne surgeon, Dr Frank, may be mentioned, which is published in the April 3, 1887, number of the *Archiv für Gynäkologie*, it enumerates the following cases of removal of the entire uterus For endometritis, four cases, for retroflexion or retroversion with fixation, three cases, *pruritus uterinus*, once, and for neuralgia and retention of urine, one case The members of the medical profession can scarcely read the account of these cases without being astounded at the amazing temerity of such proceedings

The various steps in the operation consist in, 1 freeing the cervix from its attachments, 2 hæmostasis and 3 the subsequent dressing

1 The cervix must be drawn down with forceps into the vulvar orifice if possible and the vaginal attachment severed with any cutting instrument, a bistoury, a blunt or a sharp-pointed scissors Some operators prefer one instrument, others another It is a trifling choice to make between them The vulva should be held open laterally by retractors deftly held just within the ostium, if they are thrust into the vagina too far they prevent the forced descent of the uterus If they are wide enough a perineal retractor is unnecessary Just before making the initial cutting it is well to push up the cervix (which has been drawn down) to its natural level and mark with the eye where the vagina is attached, and then draw down the organ and begin proceedings This point is rather important because no one can tell where the vaginal wall terminates and the cervical covering begins, and one is invariably inclined to begin the denudation too far away from the cervix and thus to open the bladder The encircling of the cervix can be made at once with tissues pushed away from the uterus in all directions till the broad ligaments are reached, when they will of course not be disturbed The gravest necessity exists for keeping exceedingly close to the cervix anteriorily, otherwise the operator will find that he has opened the bladder almost before he has any idea that he is dangerously near it By keeping as closely to the cervix as possible another important, nay vital, advantage will be gained, viz the avoidance of wounding the ureter, which perforates the bladder just above the middle of the anterior vaginal wall Wounding this duct complicates matters most wofully in that it necessitates the extirpation of the kidney The surest way of determining the dangerous proximity to the ureter is to discover the pulsation of its accompanying artery which is a branch of the uterine artery and is of considerable magnitude Absolute safety from wounding this important channel is guaranteed to him only who keeps closely enough to the cervix in its denudation Very soon the finger can be made to penetrate the peritoneal cavity as will be indicated by its feeling the fundus covered with the smooth, glistening peritoneum The freeing the posterior cervical wall should be prosecuted with the same care to remain close to the uterus and thus avoid opening the rectum The finger easily penetrates the Douglas cul de sac and the body of the uterus can then be explored readily Up to this point, when the peritoneal cavity is opened the bleeding is considerable though not at all alarming It is best to proceed as rapidly as possible and not to attempt to check hæmorrhage Occasionally the peritoneum is tough and cannot be perforated by the finger, then a blunt pointed pair of scissors, *closed*, can be thrust into this cavity, quickly opened and withdrawn, leaving an opening large enough to admit the finger

After opening the posterior cul de sac some operators push a soft sponge into the peritoneal cavity to remain there till the operation is terminated, for the purpose of preventing the entrance of noxious matters and of keeping the bowels up and away from possible injury It also serves the purpose upon its withdrawal of drawing down the ragged edges of the peritoneum so that in the wound peritoneum lies apposed to peritoneum, a most desirable position to be secured

At this point two proceedings lie open one is to bring the fundus down through anterior cul de sac or through posterior cul de sac—*i e*, to acutely and completely flex the uterus—and the other is, to let flexion entirely alone and to proceed at once with the treatment of the *ligamenta lata* with reference to preventing other vessels from bleeding and dividing them, and thus freeing the uterus wholly from the body Another plan resorted to before removing the organ has been, after securing the broad ligaments, to bisect the uterus from fundus to os, and to remove each half separately It must be a very exceptional case demanding this proceeding When the uterus is small flexion is an easy matter When large it is a very difficult matter, and when very large it is a feat impossible to accomplish

[1] Albert Heydenreich De l'hysterectomie Vaginale Semaine Méd, Paris 1886 vi 69 70

[2] Gazette des Hôpitaux October 12, 1886, pp 950 951

C Staude[1] recommends opening the Douglas' cul-de sac first and retroflexing the uterus completely before opening the vesico uterine cul de-sac, in order not to permit the cancerous cervix to enter the peritoneal cavity as the fundus is brought downwards The ante uterine peritoneal space thus shut off will effectually prevent the cervix entering it However, with the cervix firmly held by the vulsellum forceps it is impossible for it to ascend into the peritoneal cavity as the fundus is brought down Furthermore, if the ante uterine peritoneal space be not opened the work of securing the lateral vesicular supply must be greatly embarrassed, and the danger of wounding the ureters greatly, almost infinitely, increased

The second step in the operation consists in hæmostasis and it includes securing and dividing the broad ligaments

The devices that have been used to secure hæmastasis are almost legion Until very recently silk ligatures only were used to secure the whole mass of the ligaments or to secure it in separate divisions by the continuous or by the loop method Later the ecraséur, wire or the elastic ligature has been used The cautery has been used A separate catgut ligature for each tube has been recommended Needles with a great variety of curves have been devised The application of ligatures is attended with much difficulty, often failing in the most skilled hands

By far the best method of accomplishing hæmostasis is the snap forceps It is a sure method, it abreviates the operation and affords, additionally, perfect drainage Before using them it is always well to test the ratchet and ascertain whether they will hold permanently Occasionally forceps will unsnap and a greater calamity cannot befall an operator than to have that occur after leaving the patient Tieing the forceps together when in doubt about their reliability can be done

After the peritoneal cavity before and behind the uterus has been opened and the uterus has been completely flexed, when possible, and is retained by the *ligamenta lata* only, the latter are ready to receive the forcipressure With the forefinger of the left hand hooked over the superior margin of the left broad ligament the right hand can adjust the forceps to compress the whole width of the ligament and tighten the instrument to the last notch It is best to attach it as near to the uterus as possible and yet permit room for dividing the ligament easily at its uterine end While adjusting the forceps it is of course scarcely necessary to mention the desirability of not including in them a bit of omentum or a piece of intestine I know of no greater satisfaction in gynecological operations that the operator can experience than in tightening hæmostatic forceps on a broad ligament—a satisfaction greatly intensified when one has previously had the appalling accident occur of the shedding of the silk ligatures after the broad ligament has been permitted to contract and withdraw into the pelvis up out of sight

When the uterus cannot be flexed, the forceps have to be applied in the best way that can be devised With a much enlarged uterus the forceps can be applied to include broad ligament to the extent of the width of its jaws, that amount of ligament can be divided and up through the divided segment another pair of forceps can be pushed to include the remainder of the ligament, which in turn can be divided When the finger cannot reach the superior margin of the ligament, the lower section of each ligament can be seized and divided, when it will be found that the whole organ can be made to descend and thus the entire ligament upon each side can be divided When this procedure is necessary the difficulty of practicing it is greatly increased because of the narrowing of the vaginal space

After removing the uterus the parts should be allowed to retract in order to allow any vessels to bleed that are prevented from it by their traction By this means arterial twigs are often discovered which otherwise escape detection All further arresting of hæmorrhages can be accomplished easily with forceps This step in the operation is of vast importance, since hæmorrhage can not only result fatally, but even when not large it can become the unsuspected cause of a fatal peritonitis

The last step of the operation concerns the management of the womb The most elaborate sewing and draining of the vaginal cavity have been resorted to Stitching the peritoneum to the vaginal wall is regarded necessary by some operators One operator recently stated in his report of a case, that he stitched these two tissues throughout in order to prevent vaginal wall hæmorrhage Stitching the anterior marginal border of the rent to the posterior border and drawing the ends of the ligatures out through their centre have been very commonly done Running a purse string suture around the top of the vagina with a piece of rubber draining tube and the ligatures passing through the middle of the puckering has been used

Sewing up the vagina is wholly unnecessary in most cases These various closings of the vagina have been regarded as essential to keep back the bowels and to prevent septicæmia through the vagina Of the former there is a minimum danger When the operation is completed the superior vaginal opening collapses as thoroughly and completely as the *ostium vagina* closes The oozing opposed surfaces at once interdigitate and inaugurate the preliminary processes of union They do not lie idle for 24 or 48 hours before commencing union is set up At the end of 48 hours the top of the vagina is all closed to the passage of fluids excepting through that portion of it occupied by the means of drainage

The use of iodoform gauze in the vagina is of the utmost importance and when wrongly used is a source of danger The vagina must be absolutely aseptic, and herein the gauze filled with iodoform becomes of such great service Stuffing the vagina too full of this agent keeps apart the walls of the top of the vagina and prevents their union

A CASE OF CHRONIC PANCREATITIS, WITH SYMPTOMS RESEMBLING MALIGNANT DISEASE

Read before the Section for Clinical Medicine, Pathology, and Hygiene, of the Suffolk District Medical Society, November 9, 1887

BY E. L. CALL, M.D.,
OF BOSTON.

Mrs B., age 62, widow, was first seen February 24, 1886. She was of medium height and weight, her skin was sallow, and her countenance haggard and anxious. Her habits of life were regular, and her hygienic surroundings good. She said she had been well till within the past three or four months, but more searching inquiry showed that her appetite had been very capricious for a number of years, and that during the last year she had lost strength and a moderate amount of flesh. Her diet had been mostly of the saccharine and starchy foods, as she had always disliked meat. For the past few months physical exertion of any kind had tired her out of due proportion, and during the last few weeks even moderate exercise had been followed by breathlessness and beating in the arteries of the neck. There was complete anorexia, and the bowels were very constipated.

The physical examination was as follows. Skin, a muddy yellow, tongue, rough, slightly coated, lungs, normal, heart, normal in size and position, moderate blowing murmur throughout the cardiac area, most marked over the base, abdomen, normally resonant, liver dulness normal, no increased spleen dulness, pelvic organs, normal, urine normal.

In consequence of the negative result of the examination, the case was regarded as one of profound anæmia, and the treatment was directed toward regulating the bowels and assisting nutrition by easily digestible food and some of the most assimilable forms of iron.

The gravity of the symptoms increased rapidly, the simple act of rising from her chair caused dyspnœa, food of all kinds was very repugnant, the skin grew more sallow and the feet œdematous. She vomited occasionally, especially after any unusual movement. Temperature 100°, pulse weak, 90 to 100. This rapid change for the worse made me feel that the case must be either one of pernicious anæmia or some concealed organic disease, and I therefore asked for a consultation.

Dr R. T. Edes saw the patient with me, March 16. He did not thing the anæmia profound enough to warrant a diagnosis of pernicious anæmia, but as he could find no proof of organic disease, he advised full doses of liq. pot. arsen., and gave a very guarded prognosis. A microscopical examination of the blood showed the red corpuscles notably diminished. No increase of white corpuscles, and none of those irregular forms of red corpuscles characteristic of pernicious anæmia. The patient was kept in bed and fed *per rectum* as well as by mouth.

She improved for a time under this regimen, the dyspnœa becoming less troublesome, so that during part of April and May she was able to go down stairs, and to ride out occasionally. In fact, the dyspnœa did not trouble her again to any amount till just before her death. I never felt, however, that the improvement was permanent, for her color remained bad, and she did not gain flesh nor appetite.

Early in July she complained of fluttering in the epigastrium, and her distaste for food was so great that only the force of a strong will enabled her to eat or drink. The abdomen was again examined, slight increase in liver dulness was noted.

On August 16, she had a sharp attack of hepatic colic followed by intense jaundice, and so much nausea that she was fed entirely by rectum for five days. She rallied very slowly and now began to lose flesh quite rapidly.

On October 14, she had another attack of hepatic colic, and passed a gall-stone the size of a pea. After this the signs of digestive disturbance were more marked. She complained constantly of a burning pain under the lower end of the sternum coming on about two hours after eating. She also complained of a feeling of weight in the bowels when she sat up, as if some heavy body were dragging from the spine. As she was certainly the least nervous or imaginative person that I ever met, these symptoms deserve more attention than they would in ordinary cases.

The bowels were either constipated or relaxed. The stools varied, being sometimes perfectly normal in appearance, sometimes sticky and putty-like, sometimes gray in color, often they contained undigested food. Throughout her illness every stool was examined by her daughter, an unusually intelligent lady, and I saw many of them myself, but never could see or hear of any of the fatty stools considered to be characteristic of pancreatic disease.

Early in February, she began to vomit irregularly and complained constantly of distress after eating. She never had another paroxysm of hepatic colic, but she grew deeply jaundiced, vomited constantly for five days, the feet and limbs became œdematous, the pulse rose to 120, and death seemed imminent. During all this time no tumor of any kind could be felt in the abdomen, nor was there any tenderness nor tympanites except just after the attacks of colic. It seemed to me, however, that there must be some disease, probably malignant, in the region of the duodenum, liver or head of the pancreas, but wishing to get all the light that greater experience could give, I asked Dr M. Wyman to see her with me. Dr. Wyman thought the case was either one of pernicious anæmia or malignant disease, probably the latter.

The vomiting gradually ceased and she rallied slightly again, and from this time, January 4, till her death, February 14, it did not recur to any extent. She now began to suffer from what she called "nervous twitches." She insisted that she had no pain, but she lay as if prostrated, moaning with every breath, her features pinched and deathly pale. In fact, her appearance was exactly as when she was suffering from hepatic colic, except that there was constant twitching of the feet and legs, and oc-

casionally of the arms These movements were to a certain extent, but not entirely, under the control of the will The attacks came on at first only occasionally, but they grew more and more frequent, until during the last two weeks of her life, it was necessary to keep her constantly under the influence of sedatives to give her any rest from them She grew gradually weaker, and died February 14

Autopsy, twenty-six hours after death Rigor mortis well marked Skin a dirty yellow Body and limbs much emaciated Owing to circumstances which so often hamper the performance of autopsies in private families, I was only able to examine the abdominal cavity

The muscular layer of the abdomen was very thin The abdominal cavity contained a small amount of clear serum The intestines looked very anæmic The small intestines were contracted, the large intestines unusually long and somewhat distended, the walls in some places so thin as to appear almost transparent No trace of peritoneal adhesion or inflammation

Liver slightly enlarged, rather pale, yellowish, surface perfectly smooth, but rather firm in texture

Gall-bladder the size of a large pear containing three large and many small gall stones Bile very dark and viscid

Stomach empty Walls very thin, not the slightest appearance of malignant disease in the stomach or duodenum Upon raising the stomach the pancreas was seen, larger than normal, dark gray in color, and so firmly adherent to the vertebræ and posterior abdominal walls that it was detached with great difficulty The attachment to the duodenum was also over a larger surface than usual, the gastro splenic omentum much thickened Upon removing the pancreas, it looked so large and firm that I felt assured that there must be a deposit of cancer in the head, and that the diagnosis of malignant disease was correct The specimen was placed in alcohol for further examination, but it was found impossible to harden it, in fact, it grew softer, and large quantities of fat seemed to have been dissolved out by the alcohol and floated upon the surface A microscopical examination, in which I was kindly assisted by Dr Blodgett, showed a large increase of connective tissue, an abundant deposit of pigment, with very little trace of acini or glandular epithelium, a considerable amount of fatty degeneration The specimen gives a very poor idea of its appearance when removed from the body Its size has diminished at least one-half, by its seven months' immersion in alcohol, while the texture is softer and more friable The portion of duodenum attached shows the opening of the ductus communis and the canal of Wirsung The gall ducts are very much dilated The opening of the portal vein is seen toward the head, while the superior mesenteric artery runs along its posterior surface, and the splenic along its upper border

I bring the case before the Society as one of pancreatic disease, although I am quite aware that it may be an open question how far the condition of the pancreas was answerable for the symptoms There is so little known of the pathology of this organ, that it seems right that every case in which an abnormal condition is found, should be recorded Almost all reported cases are those of carcinoma, in which it is very difficult to separate the symptoms common to many carcinomatous growths from those due to injury of the gland Moreover, in most of these cases the disease has extended before death to neighboring organs

Experiments of removing or destroying the pancreas in animals, show diverse results While in some, rapid emaciation, fatty diarrhœa, and death from inanition, rapidly follows, in others the pancreatic secretion seems to be replaced by some other digestive fluid, so that the nutrition of the animal suffers very little This is notably the case in the experiments lately published by Senn in his articles on "Surgery of the Pancreas "

The chief symptoms supposed to indicate pancreatic disease are rapid emaciation, jaundice, diarrhœa and constipation, fatty stools and cœliac neuralgia, but no one of these symptoms seems to be invariably present, and only one, the fatty stools, pathognomonic In about twenty five cases which I have been able to collect, of disease of the pancreas, mostly malignant, in only two were the fatty stools prominent, though doubtless in many search for them was not made, as the disease was not diagnosed before death

A symptom mentioned by Friedreich in "Ziemssen's Handbook," and by Starr in "Pepper's System of Medicine," is a feeling of weight in the epigastrium, particularly on assuming the erect position, as if a heavy body were pulling from the spine This symptom was constantly complained of by my patient, so long as she was able to sit up I cannot help thinking that the paroxysms of nervous distress which were the cause of so much suffering to her, were some form of nervous disturbance produced by pressure on the nerve structures surrounding the pancreas, and were analogous to the attacks of cœliac neuralgia mentioned by many authors

Although all writers on pancreatic disease describe a chronic hyperplasia of the connective tissue of the pancreas as one of its diseases, I can find the record of only one case which seems somewhat similar to the one I have here described This was reported by Dr Tyson in the *Philadelphia Medical Times* in 1882 The case was that of a lady 68 years old, who had always been well until an attack of pneumonia in February, 1880 From this time she had more or less disturbance of the bowels In July, 1881, she was seized with severe diarrhœa and clay colored stools This was quite persistent, and accompanied by irregular distension of the abdomen, apparently from areas of flatus Later, a small indistinct lump was discovered below the umbilicus and to the left The diarrhœa continued and the stools were distinctly fatty She emaciated rapidly, and died March, 1882

At the autopsy, the lump had disappeared behind the stomach, but was found to be the head of the pancreas, which was unusually resisting but not much enlarged Upon examination the secreting

structure of the pancreas was found to be nearly all atrophied and its place occupied by a fibrous tissue In this case, also, the organ was so much shrunken and altered by the preserving fluid as to present a far less striking appearance than when removed from the body

But in addition to the condition of the pancreas itself, I wish to call your attention to the parts surrounding it, as it seems to me that we may find there an explanation of some of the symptoms not otherwise accounted for The adhesions between the head of the pancreas and the vertebral column were so firm that I was obliged literally to dig the gland out of its bed The connective tissue seemed almost leathery in its toughness and resistance

You will remember that the coeliac axis gives off its branches just at the upper border of the pancreas, the semilunar ganglia of the solar plexus lie partially behind the gland, while the superior mesenteric is given off from the aorta just at its lower border In this case, as will be seen by the specimen, the superior mesenteric is given off above the pancreas and runs across its whole posterior surface, and therefore could hardly fail to be compressed between it and the spine, where the adhesions were so firm as in this case Even a moderate amount of compression on the artery supplying the whole of the small intestines would probably modify their nutrition and render their digestive fluids unable to supply the want of pancreatic secretion, as it probably does in some cases The semilunar ganglia would be even more easily compressed than the arteries Since they are the sympathetic nerve centres which modify the nutrition of all the organs of digestion, any injury to them would probable affect the proper performance of the function of those organs

There is no doubt that the attacks of hepatic colic were instrumental in hastening the fatal termination of the case

I suppose it may be asked whether this was not really a case of pernicious anæmia and the condition of the pancreas, etc , only a secondary result of the anæmia, instead of being its cause Against this speaks the age of the patient, her comfortable circumstances and regular life, the high degree of emaciation, the absence of fever, and the fact that at the autopsy the organs, though anæmic, had not that absolutely blanched appearance described as characteristic of pernicious anæmia

I hope, however, that those who have had more experience than I have in this disease will give the Society the benefit of their opinion on the question

MEDICAL PROGRESS.

SURGICAL TUBERCULOSIS —(See the numbers of THE JOURNAL for Oct 29, Nov 5, 12, 19, 26, Dec 3, 10 and 17)

45 Not without consideration for surgery is the question, in how far does tuberculosis of itself cause suppuration, and in how far are the softening and suppuration of tuberculous foci favored by the entrance of septic material, that finds a suitable soil in the dead tissue masses of such foci?

The regularity of softening and ulceration in the tuberculous conditions of the respiratory and intestinal tracts, contrary to the extraordinary frequency with which tuberculosis of bones and joints heals without suppuration, or at least exists for as much as a year without suppurating, is very striking The older authors often asserted that high fever accelerated the softening of the tubercle

46 With regard to the localization of the foci in the different organs, regions of the body and tissues, tuberculosis shows the greatest difference in children and adults, and in regard to the curability and the danger to life, exact statistics on this point are desirable It is well known that spina ventosa occurs only in small children, and tuberculosis of the shoulder joint almost exclusively in adults, and the tuberculous suppuration of the knee joint, running a very torpid course, is found almost exclusively in the latter

In children the process of cure is very much more ready than in adults Tuberculous diseases also recede without suppuration very much more frequently in children Even the most severe tuberculous bone and joint affections, complicated with the most extensive disturbances, may heal spontaneously in children Here conservative surgery has made a great field, while in similar cases in adults a cure can be obtained only by removal of the diseased portion, and often only by amputation Tuberculous bone and joint affections in children are easily self circumscribed The diffuse suppuration of the whole carpus, as frequently occurs in adults, especially in elder persons, is scarcely ever seen in children And when a rather rare case of suppurating tuberculosis of the carpus is seen in a child, the process remains limited to that joint All the cases that I have seen in younger children were cured by drainage and scraping Similar conditions prevail in the foot From puberty onwards the prognosis becomes gradually worse The cases become more numerous in which conservative principles cannot be applied

Tuberculous focal affections of external organs combined with tuberculosis of the lungs are very much less frequent in children than in adults In a somewhat old person, that has, for example, caries of the wrist, it is an exception that he has not already or soon will have tuberculosis of the lungs

47 The battle as to the identity of tuberculosis and scrofula is still being fought It must be first settled what forms of the lighter so called scrofulous affections are produced by the tubercle bacillus In a case of eczema of the arm that, I believe, every dermatologist had diagnosticated as eczema, and which I examined only because scrofulous softened cubital glands were present, I found tubercle bacilli in the eczematous masses of epidermis scraped off

We must next find out in how far chronic inflammations, hyperplasias, and especially tissue changes that offer a favorable soil for the tuberculous virus, are caused by scrofula It seems that such a relation is proved by the lymphatics

Finally, it must not be overlooked that in the dispute as to the identity of scrofula and tuberculosis the question is often placed improperly and illogically Tuberculosis one generally thinks of as a local process, and scrofula more as a certain unknown constitutional and nutritive anomaly, as a special disposition, diathesis, as an hereditary predisposition, which in great part coincides with what is taken for tuberculosis

A person that shows not the slightest local change and no deviation from the normal on the most rigid examination of his organs we say is not tuberculous, but we reckon as scrofulous a now blooming and completely healthy child that has already gone through a series of affections that we call scrofulosis And we would perhaps even call it scrofulous if only a part of his relatives had suffered from scrofulous affections, and tuberculosis was in his own family and house

48 It cannot be doubted that certain drugs applied locally to tuberculously diseased tissue exert a curative, and perhaps even a specific influence The favorable action of preparations of mercury on lupus, for example, is not to be disputed Still, opinions differ very widely, and a further and comparatively test of such drugs is very much to be desired With the preparations of mercury may be mentioned especially iodoform, iodine, arsenic, lactic acid, etc What has been said applies with still more force to the internal use of such drugs —*Langenbeck's Archiv*, Bd 33, Hft I

USTILAGO MAYDIS AS AN OXYTOXIC —DR W A N DORLAND, of the Philadelphia Hospital, after a study of ustilago maydis, summarizes as follows

1 *The toxicology and physiological action of the drug*—No cases of poisoning in man by the drug are on record That it is, however, possessed of toxic properties in large doses has been proved by Mitchell He found that in the lower animals, in large doses, it acted violently upon the spinal cord, paralyzing first the sensory, later the motor tracts, finally involving the motor and probably also the sensory nerves Like ergot, then, it is probable that the chief force of the drug, in toxic doses, is expended upon the nerve centres, producing a toxic paralysis

The action of ustilago upon the uterus has been more carefully noted After the ingestion of a sufficient amount, in from twenty minutes to half an hour, the pains, if present, are increased in severity, in frequency, and in duration, presenting a marked *clonic* character, following each other in frequent succession, with a decided intermission between each In this respect it differs decidedly from the action of ergot, which, in full doses, produces one continuous, *tonic* spasm of the uterine muscle It is this property of ergot which has, when administered before the delivery of the placenta, produced in so many instances the irregular contractions of the uterus, of which the hour-glass is a well known example The employment of ustilago seems to be entirely free from such unpleasant complications In addition to being a valuable adjuvant in stimulating weak uterine contractions, ustilago seems to possess the property, which some years ago was ascribed to quinine, namely of exciting uterine pains when entirely suspended

As to the time required for the action of the drug to become apparent, it may be said that it differs in different cases, depending, undoubtedly, upon the rapidity with which it is absorbed from the gastro-intestinal tract and carried into the system In only two instances did it require over thirty five minutes before the ustilago acted upon the uterine tissues, and in one case most of the drug was ejected by emesis In the remaining seven cases the average time required was twenty five minutes

The effect produced by ustilago upon the other unstriped muscular tissues of the body has not been inquired into Probably it produces the same increase of intestinal peristalsis and the same rise in the arterial pressure due to vaso motor spasm as is produced by ergot This is yet open to investigation

2 *The indications for the employment of the drug* —We shall consider the first indication for its use to be the failure of the pains, with *complete dilatation of the os uteri* In none of the cases was the drug employed until the pains of labor had either become so weak that they were inefficient to accomplish the expulsion of the fœtus, or until they were entirely suspended This, then, we consider the second indication for its use, namely, the *inefficiency or entire suspension of the parturient pain* After the ustilago had been taken, it may also be noticed that in no case was there the slightest tendency toward a post partum hæmorrhage In each case, after the expulsion of the placenta, the uterus remained in a state of firm contraction While, during the three months the great majority of the remaining cases, in which the customary ergot had been employed, showed no tendency whatever toward this alarming accident, however, in two instances was there such an occurrence demanding prompt attention The third indication, then, for the employment of ustilago we shall consider to be *a condition of uterine inertia threatening or producing post partum hæmorrhage*

3 *The dose and mode of administration* —The preparation of ustilago employed in all reported cases, as well as in our own, was a good fluid extract The dose of this varies from one half to two drachms, one drachm being a fair average This may be repeated at intervals as required Should it be necessary, it may be used hypodermatically in doses of from five to fifteen minims

Finally *The advantages of ustilago over ergot* — The employment of ustilago seems much to be preferred to that of ergot It does not produce irregular contractions with all the consequent complications and sequelæ, containing but 2½ per cent of fixed oil, while ergot contains from 25 per cent to 28 per cent, the dangers of absorption are reduced to a minimum, and finally, as it can be procured at a cost of 50 per cent less than that of ergot, it seems to be on a fair highway toward the supplanting of the latter in obstetrical practice, should the results of the investigations thus far be confirmed by subsequent researches —*Medical News*, Nov 5, 1887

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE	$5 00
SINGLE COPIES	10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

MEDICAL LEGISLATION AND THE STANDARD OF GENERAL EDUCATION

In THE JOURNAL of the 17th inst, attention was called to the necessity of securing more uniformity in the laws enacted by the several State Legislatures for the regulation of medical education and practice, and to the fact that a special committee had been appointed by the Section of State Medicine to prepare the draft of a law for that purpose, and report the same to the Section during the next annual meeting of the American Medical Association It was also suggested that any law, to be of real value, must be so framed as to secure the actual accomplishment of three leading objects, namely a fair and creditable standard of general education for the student before being permitted to enter upon the study of medicine, a thorough knowledge of all the recognized branches of medicine, and a competent and impartial tribunal or Board, in each State, to determine by adequate practical tests when the two preceding standards or requirements have been complied with by each individual candidate asking for admission to membership in the medical profession Fair investigation will show that no law can be framed, the execution of which will materially improve the education and usefulness of the medical profession, unless its provisions are such as shall establish and enforce a standard of education as a prerequisite to the study of medicine embracing, in addition to the ordinary elementary branches, at least a thorough knowledge of mathematics, physics, the natural sciences and English literature

The law, to be of value, must not only specify plainly the minimum requirements for commencing the study of medicine, but it must provide the tribunal in each State whose duty it shall be to examine and register all persons proposing to commence the study of medicine, and to issue certificates to those only who are found qualified in accordance with the standard given in the law, and no *time* shall be allowed as having been spent in pursuing medical studies until such registration and certificate has been obtained To accomplish this does not necessitate a multiplication of State Examining Boards The same Board that decides the qualifications of the students in medicine and awards to them the license to practice, should also examine and decide upon the preliminary qualifications of those proposing to study medicine If it be said that the requirement compelling every person proposing to study medicine to spend the time and money necessary to demonstrate to a State Board of Examiners his fitness for entering upon the important field of professional study, would deter many from making the attempt, the obvious answer is, so much the better for all the parties interested Better for the individual to be thus stopped at the threshold and turned into some vocation better suited to his capacities, than to pass him through the door without a question and permit him to spend three years of valuable time, with several hundreds of dollars, and then reject him, or, still worse, pass him through the second door into the ranks of a profession already crowded to excess, where little else than a life of disappointment and poverty awaits him Better, far better also would it be, for both the profession and the community, if such a reasonable barrier were interposed where the first step towards professional study is to be taken

It would be the most effectual mode of compelling all parties to recognize the fact that the successful study and practice of medicine actually requires a preparatory mental discipline that can be acquired only by a fair general education It would not only materially lessen the number entering upon the study of medicine and thereby aid in lessening the evil of overcrowding the professional ranks, but it would do it by turning aside the very class whose free admission heretofore has done more to lower the standing and usefulness of the profession than any other influence that could be named There has been manifest a somewhat persistent disposition to hold the medical colleges responsible for the proper preparatory education of the students they admit to their halls Experience, however, long since demonstrated its impracticability It is true that we have several medical colleges, chiefly connected with established universities, the faculties of which have faithfully

endeavored to maintain some standard of preliminary education as a condition for admission to their instruction, and these will continue to do so, while they see year after year the same persons whom they have refused matriculation, go directly into other colleges where no preliminary questions are asked A very few years since the Illinois State Board of Health gave notice that it would not recognize any medical college as in "good standing" that did not require a certain standard of preliminary education nor issue a license to practice in that State to any one founded on the diploma of such college In consequence a large number of colleges inserted a paragraph in their next annual announcement stating that the proposed standard of preliminary education would be required, and thus retained their "good standing" with the Illinois State Board But practically the clause thus inserted had the same kind of influence, though less durable, on the educational qualifications of the students admitted to the colleges, that the fence-post, clothed with an old coat and hat, does for a "scare-crow" in the farmer's cornfield It frightened a few of the more timid away for the first year, until they had time, by correspondence or by the names of acquaintances they saw in the list of students contained in the next announcement, to learn that the preliminary examinations were of such a character that "no applicant had yet failed to pass " If any of our readers are inclined to place value on the preliminary requirements of such colleges as have been induced to insert the clause relating thereto in the annual announcement in obedience to the demands of the Illinois State Board of Health, we commend to their perusal the results of the careful and well devised researches of Dr J P Garrish, of Portland, Maine, presented at the last annual meeting of the American Academy of Medicine, and published a few months since in several of the medical journals If we are to have further legislation relating to strictly medical matters, let the profession exert its influence in favor of only such statutory provisions as will prove of substantial benefit in improving the educational status of the profession, and thereby proportionately increasing its usefulness and honor

EYE-TROUBLES AND NERVOUS DISEASE

More and more during the past few years, has the attention of the profession been called to the frequency with which functional or reflex disturbances are caused by disturbances of vision The latest issued contribution to this subject (of any considerable length or pretense) is a work by DR GEORGE T STEVENS, of New York, to which was awarded the prize of the Royal Academy of Belgium in 1883, and that is now presented in the English language The work is based on a large number of cases of nervous disease, both in private and hospital practice The conclusion that he arrived at in his investigations is thus formulated Difficulties attending the functions of accommodating and of adjusting the eyes in the act of vision, or irritations arising from the nerves involved in these processes, are among the most prolific sources of nervous disturbances, and more frequently than other conditions constitute a neuropathic tendency

It will be observed that the proposition is not exclusive, but that it recognizes any and all causes of nervous irritation, and that while the influences indicated by it are held to be pre-eminent, they are not held as being exclusive permanent causes "Let it be remembered," says the author, "that it has been universally conceded that the nature of the neuropathic tendency is unknown If one pre eminently important tendency is here demonstrated, it is not to be rejected because it may not include the whole "

Keeping this in mind, we may now speak of some of the nervous troubles that Dr Stevens has found to originate from ocular disturbances

In regard to these troubles, probably more has been written of *headache* from eye trouble than of any or all other disorders arising from ocular disturbance Dr Stevens cites cases of chronic headache relieved by removal of the irritation caused by 1 Hypermetropia, with insufficiency of the external recti, 2 Astigmatism, with enfeebled adducting force, 3 Enfeebled energy of the muscles of accommodation, 4 Insufficiency of the external recti muscles uncomplicated with any very important refractive error From this it appears that these conditions may act as disposing causes of headache, and that the removal of the irritation caused by such conditions is sufficient to give permanent relief The percentage of chronic headaches permanently relieved was 83 6, improved 12 4, and not cured 4 No cases of simple asthenopia or of temporary headache are included in this analysis In regard to migraine, it is significant that in a few cases in which the fundus of the eye has been examined ophthalmoscopically during the period of visual disturbance, the retina has been found pale and brilliant, the optic disc unusually white, and the main arteries irregularly contracted in their course In these cases the field of vision is more or less contracted Such cases, when dependent upon visual troubles, are

more difficult to relieve, according to Dr Stevens, than ordinary chronic headaches, as there is often a complicated state of refractive trouble and muscular insufficiency, demanding greater care and judgment in correcting the ocular conditions

As concerns the relation of neuralgia to ocular troubles, the author gives an analysis of 100 cases of neuralgia seen by him in fifteen months 12 were not subject to important ocular defects, or were seen only once, 3 would not follow the advice given, of the remainder 83 33 per cent were permanently relieved, 11 76 per cent materially improved, and 4 71 per cent not relieved by correction of the eye troubles On comparing the family history and physical conditions in many hundreds of cases of neuroses, the author concludes that hereditary neuroses are not transmitted from parent to child directly, that they are the manifestations of transmitted physical peculiarities that render difficult the performance of certain important functions, and that of the hereditary physical defects that thus tend to develop neuroses, anomalous conditions of the eyes are among the most frequent and important, and these conclusions are well maintained in regard to neuralgia. The author also gives records of several cases of "spinal irritation" and of neurasthenia cured by correction of ocular troubles

Pye Smith found that of 136 choreic patients at Guy's Hospital, 106 were between the ages of 6 and 15, and 62 of these were between the ages of 6 and 10, so that almost half were at the age when children enter school, and almost all were children of school age Dr Stevens says that his researches show that the majority of cases of chorea occur among children that are hypermetropic Of 118 cases examined in private practice, there was simple hypermetropia in 78, hypermetropic astigmatism in 13, mixed astigmatism in 5, unequal myopia in 6, and myopic astigmatism in 2, and associated with these conditions in a considerable number of cases, there was more or less muscular disability From a careful study of the cases that he has examined, and of the results of treatment of ocular troubles found, the author asserts the direct relationship between these ocular troubles and chorea (more especially chronic chorea, since no conclusions of value could be drawn from a small number of cases of acute chorea, that has a tendency to recover spontaneously in a few weeks) And after reading the records of the five cases given by the author, one is not much inclined to quarrel with the conclusion that chorea is emphatically a nervous trouble depending upon ocular conditions

In regard to the relation of eye trouble to epilepsy the author considers that form of epilepsy only that does not depend upon visible lesions Examinations of ocular conditions were made in 140 cases of epilepsy, 85 of which were in private practice The general result was the finding of refractive anomalies in a considerably larger ratio of cases than was found by Cohn in his examinations of the eyes of school children, in 100 consecutive cases there was hypermetropia (including hypermetrophic astigmatism), in 59 cases, myopia (including myopic astigmatism in 23 cases, and emmetropia, or refractive errors less than 1 D in 18 cases) In four of the cases in which notable errors of refraction were not observed, atrophy of one of the eyes existed "In the greatest number of cases examined in private practice very marked insufficiency of the motor muscles of the eyes was found, and it may be here observed that, so far as ocular irritations are concerned in the origin of a tendency to epilepsy, muscular irregularities are doubtless much more efficient than refractive anomalies The proportion of refractive errors stated above would not of itself prove a relation between the state of the eyes and the epileptic condition, although the proportion is notably in excess of that found by examination of those in health This circumstance, however, taken with that of a state of insufficiency of the ocular muscles existing very generally, renders it probable that the ocular defects may be in relation to the epileptic tendency " This probability becomes an exceedingly strong one when we consider the results of treatment based upon the supposition that epilepsy may be in direct relation to the ocular condition Of the cases seen in private practice 34 only were treated and observed for any length of time beyond one or two visits, 5 withdrew from treatment before obtaining any relief from important ocular defects, and the remaining 29 were treated only by the removal of the ocular defects, 14 of these may be considered well, 2, still under observation when the memoir was written, are believed to be permanently relieved, 3 others still under treatment, have received such marked relief that it is believed that an entire discontinuance of the malady may be expected, 7 have received temporary relief, 2 showed no improvement, and 1 that had shown some improvement, died of accident four months after the first visit The question of the influence of drugs is thrown out in these cases, since some patients had taken none for some time before coming under treatment, and in cases in which drugs were taken up to the time that treatment was begun they were at once discontinued The 12 cases re-

corded by Dr Stevens are exceedingly interesting

It is quite conceivable that disturbances of vision must react upon the mental as well as upon the sensory system Dr Stevens gives details of four cases of mental disorders relieved or cured by correction of visual anomalies Two of these cases are illustrated by photographs, taken before and after correction of the eye trouble, that show more than could possibly be told

---

In several hundred of his cases Dr Stevens has made a careful study of the heredity of the patients The list contains consecutive cases of nervous diseases in which the family record was ascertained, and in which refractive errors of 1 D or more, excluding cases of simple myopia, were found, muscular insufficiencies being excluded All the cases were those of adults Most of the deaths in the families of these cases have been from very chronic diseases or from sudden strokes like apoplexy or diseases of the heart In 207 deaths 89 were from phthisis (more than 43 per cent), about 7 per cent died from Bright's disease, and 9 per cent died from paralysis and apoplexy—the usual death rate from these diseases in New York being a little over 24 per cent, about 4 per cent, and 5 per cent respectively From a careful study of these histories it would seem that in families with a high degree of refractive errors there is a great frequency of nervous disorders and organic lesions, of consumption and Bright's disease, and that the higher the grade of refractive anomalies, the greater is the proportion of phthisis and Bright's disease

---

AMERICAN RHINOLOGICAL ASSOCIATION —At the last annual meeting of this Association, September, 1887, the following officers were elected for the current year President, Dr C H von Klein, Dayton, Ohio, Vice-Presidents, Drs R S Knode, Fort Wayne, Indiana, and A G Hobbs, Atlanta, Georgia, Secretary and Treasurer, Dr John North, Keokuk, Iowa, Librarian, Dr N R Gordon, Springfield, Illinois The sixth annual meeting will be held in Cincinnati, Ohio, September, 1888

THE CENTRAL WISCONSIN MEDICAL SOCIETY will hold its third quartely meeting in the Capitol, at Madison, December 27th, 1887 A good program of work is offered President, L V Lewis, Secretary, C S Sheldon, of Madison

---

COMPLIMENTARY —The well written and valuable work of Dr H Gradle, of Chicago, on "Bacteriology," has attracted attention in Japan, and been translated into the language of that country

---

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, November 3, 1887

THE PRESIDENT, T M DRYSDALE, M D, IN THE CHAIR

DR ROBT H HAMILL reported a case of

PUERPERAL MALARIAL FEVER, SIMULATING SEPSIS

In the *Amer Jour Obst*, April, 1880, Dr Fordyce Barker called attention to a peculiar febrile derangement, known as "puerperal malarial fever" It is of paramount importance to the obstetrician to know whether or not he has to deal with a disease that is the result of carelessness, or one of miasmatic origin The following case, which I wish to add to the list, seemed to be caused by a miasmatic influence, rather than one of septic origin I shall only give the most prominent points in the case, which led me to believe that it was of malarial rather than septicæmic origin The patient was delivered of a premature still born child, labor being complicated by placenta prævia and induced It was reported at the September meeting of the Society Twelve hours after labor had ended the temperature had risen to 101 5° F, but the patient was otherwise in good condition The following day her temperature had fallen one degree In the evening of the third day she had a severe chill lasting fully twenty minutes, and followed by fever and profuse sweating From the fact of labor being complicated as before stated and version having been performed, I very much feared I had a case of sepsis to deal with, but after learning that during her pregnancy she suffered considerably, at times, from an ill defined feeling of lassitude, and "an aching of her whole body," and further, that the street in which she had lived had been in miserable condition, stagnant pools of water being allowed to remain, thus creating a favorable nidus for the germs of malaria, I felt much relieved In addition to this history, and much to my delight, the woman had another severe chill followed by the fever and sweating stages These chills continued occurring daily until the ninth day, decreasing in severity each day At times there was slight delirium Almost from the first the patient was taciturn and later on became very weak, with a feeble rapid pulse There was no pelvic pain or tenderness, and very little if any tympany No odor to the lochia, which was normal in quantity Vagina and appendages perfectly healthy The blood was not examined because quinine had been given from the first Very little change took place in her condition until the seventeenth day, when there was an abatement in all her symptoms, and convalescence was very rapid The treatment

consisted chiefly in the administration of large doses of quinine and stimulants The amount of quinine taken without producing any symptoms of cinchonism was greater than I have ever known In one dose she got 30 grains, followed in two hours by 30 grains more Quinine seemed to have no effect until used in the form of Warburg's tincture, notwithstanding it had been given in one large and in smaller oft repeated doses After the patient began to convalesce she did not have an unfavorable symptom, and is now fully recovered

DR J L LUDLOW spoke of the history of Warburg's tincture and of the difficulty of obtaining a preparation in accordance with the original recipe He had succeeded in having an exact preparation made by a druggist of this city, and it had yielded him results far better than he could obtain with quinine or any other combination of it He had used it at Eddystone with great success

DR DRYSDALE has had wonderful effects from Warburg's tincture

DR B C HIRST on

CATHETERIZATION OF THE URETERS

After seeing the ureteral catheters that were shown by Dr Kelly at the last meeting of the Society, and hearing his commendation of them, a case came under my observation in the Maternity Hospital that seemed eminently suitable for the application of these instruments as an aid in arriving at a correct diagnosis The clinical history of the case is briefly as follows A young prima gravida was found to have both pus and albumin in her urine, which condition persisted after delivery The case was treated as one of cystitis by vesical injections, but without much benefit Some three weeks after the delivery, the quantity of urine excreted in *twenty-four hours* became decidedly lessened, while the amount of pus became both actually and relatively much decreased At the same time the temperature rose to 104° and there was considerable pain over the region of the right kidney This history would, of course, have led one to suspect "lithogenic pyelitis" resulting in the formation of a stone in the pelvis of the right kidney, which had suddenly plugged up the outlet from the kidney and had thus diminished the quantity of urine and decreased the amount of pus An answer to the following questions was desirable 1 Was the *right kidney* chiefly affected, or was the pain on the right side referable to a morbid condition of the left kidney? a possibility to which attention has been called, especially by Knowsley Thornton 2 Were both kidneys diseased or was one healthy? 3 Did the pus really come from the kidneys or was it confined to the bladder? I was able to solve these problems by the use of the ureteral catheters which Dr Kelly was kind enough to lend me The ureters were made out without difficulty by abdominal palpation, and the catheters, first the metal and then the flexible, were introduced with ease, the flexible catheter being pushed up the right ureter a distance of 8½ inches The specimens of urine collected in separate test tubes from each kidney showed, on inspection, a much greater turbidity in that from the right than in that from the left kidney A microscopic examination revealed pus in both specimens, but in that from the right side in much larger amounts than in the specimen from the left kidney In the urine from the left side a well defined granular cast was found I can say, then, 1, that the pus came from the kidneys, 2, that both kidneys are diseased, but the right is most markedly affected, 3, that there is not only pyelitis, but pyelo nephritis in the left kidney, arriving thus at a precision in diagnosis that would be impossible without the aid of the ureteral catheter

DR HAMILL had since the last meeting palpated the ureters without difficulty, and had passed the catheter into them The ureters were about the size of the little finger

DR KELLY has, since the last meeting, operated successfully for the relief of a ureteritis in on unmarried young woman, the pelvic organs were healthy The inflammation was confined to the orifices of the ureters He experienced no difficulty in passing the catheters

DR PHILIP M SCHIEDT read a paper on the

DELIVERY OF THE AFTER COMING HEAD

"Time is the great factor in these cases It is generally considered that if the head is not delivered in from five to eight minutes after the delivery of the body, the child will be still born " Dr Schiedt took up the history of the literature of the subject from the time of Celsus, and the method of "expression" by suprapubic pressure, down through the various manual methods He deprecated the neglect of this subject by American and English authors, and entered very fully into a criticism of the methods advocated by German and French writers His own deduction from an analysis and comparison of these authorities, who widely differ in their teachings, and *from his own experience*, is that the forceps constitute "the best, quickest and safest treatment "

DR WM GOODELL had been struck by what seemed to him a great although common mistake, trying to secure flexion of the head in breech deliveries In a flattened pelvis it is better for the head to descend in a transverse position, so as to enable its shortest diameter, the bi temporal, to correspond to the short diameter of the pelvis, the antero posterior In a justo minor pelvis the operator would be justified in trying to secure flexion The fingers in the fœtal mouth are useless for good, but there is danger of breaking the jaw The forceps is the only proper aid in the expulsion of the after coming head One objection often made to their use is the loss of time involved in their application, but this does not hold The accoucheur should be acquainted with the form of the patient's pelvis The body of the child should be held away so that the forceps can be applied to the sides of the head, the handles being on the anterior aspect of the child's body Another point to bear in mind in a flattened pelvis, is the problem of bringing the head safely around the promontory of the sacrum The hand should grasp the neck of the child, the thumb being on one side and the fingers on the other, and traction should be

made so as to ease the head around the promontory before securing rotation of the face into the hollow of the sacrum After this it would be easy to make the chin engage or to apply the forceps

DR CLEEMANN has never met with any difficulty in delivering the face in head last labors

DR M PRICE makes it a rule to have his forceps ready in breech deliveries He has the body held out of the way and has had no trouble in putting in the forceps He has had but one death in a breech presentation On that occasion he had not his forceps with him

DR W S STEWART prefers breech to head presentations He has not had trouble in applying the forceps

DR LONGAKER laid great stress upon the necessity of avoiding mismanagement in the early stages of a breech delivery, there should be no immediate haste If the legs are seized and drawn upon the body is quickly delivered without securing dilatation of the os uteri and the arms become extended beside the head in the grasp of the lower segment of the uterus Forcible extraction at this stage is a frequent cause of extensive laceration and has caused death of the mother He agrees with Dr Goodell as to the treatment of these cases in flattened pelves the adaptation of the bitemporal diameter to the direct conjugate should be secured and the obliquity of Nagele should be maintained until the anterior base has well descended into the cavity of the pelvis The late Dr H H Smith laid great stress on the propriety of using the forceps to assist in the delivery of the after coming head In applying the forceps, flex the body of the child towards the dorsum, and the handles of the forceps should be on the anterior aspect Pressure over the head of the child, while the body is swept toward the belly of the mother is not a good or safe method, the amount of traction required to extract the head is too great for the neck to bear The forceps should be in readiness to apply as soon as the body has escaped from the vulva

DR EDWARD WILSON thought it a common mistake to hurry the delivery of the body of the child When dilatation of the os is complete the child will descend with the arms folded on the body He is as strong an advocate of the application of the forceps to the after-coming head as any man can possibly be

DR J C MORRIS could understand the defense for making traction on the lower jaw by putting one finger in the child's mouth When the buttocks are emerging, very slight traction will cause extension of the head, but if a hand is passed along the anterior aspect of the child's body and one finger introduced into its mouth the extension of the head might be prevented He did not think this defense a good one as traction on the lower jaw could not be effective He would quite as lieve have a breech as a vertex presentation The forceps should always be at hand and there is no difficulty in putting them on There is need of quick action Traction on the neck of the child may be productive of great injury He has known it to result in death, and in loss of power in the lower extremities

DR SCHIEDT wished to emphasize the necessity for the use of the forceps as the subject has been so slighted in modern medical literature

DR LONGAKER exhibited the *Ether Inhaler* and can combined, devised by Dr Young, of Bridgeport, Conn He had found it very useful in using chloroform in labor

DR BALDY took exception to Dr Longaker's statements that fresh air passed through the instrument at every inhalation and that the patient received a saturated ether vapor, as he considered them conflicting He preferred the folded, cone shaped towel

EXPLORATORY INCISION

DR MONTGOMERY reported the following case seen with Dr E R Stone

Mary G , æt 28, married, but not living with her husband She had noticed for some two months a swelling of the abdomen, this became so marked that Dr Stone had twice during this time emptied the abdomen by means of a trocar The fluid was plainly ascitic When Dr M was called the abdomen was again quite well distended, the resonance was that of ascites Vaginal examination disclosed a mass, quite resistant, situated upon either side of the uterus The rapidly recurring ascites, with the solid mass in the pelvis, aroused the suspicion of a malignant condition An exploratory incision was advised, and was made at the Med Chir Hospital, October 1, 1887 Drs Drysdale, Warder and Stewart assisting Upon opening the abdomen, two gallons of ascitic fluid were removed and the tumor presented itself It was covered with papillary growths which extended also over the posterior surface of the uterus, into Douglas' pouch and over the whole left side so that removal was out of the question The abdomen was thoroughly sponged out, and the wound closed and bandaged The following day frequently repeated doses of salines were given to produce watery evacuation and drain the peritoneum She was allowed but little liquid There was slight elevation of temperature, reaching 100° on the second day The wound had healed completely at the end of the week She left the hospital in two weeks, much improved in appearance and without any appearance of return of the ascites Since her return home there has been a reaccumulation Microscopical examination showed the growth to be an ovarian *papilloma*

DR MONTGOMERY exhibited an

INTRA-UTERINE FIBROID

as large as an orange It had been removed from a single lady æt 45 She had been suffering from hæmorrhage for over three years but had never been subjected to an examination A fibroid tumor was found projecting into the uterine cavity from the posterior wall She was admitted to his private hospital on June 22, and a large luminous tent introduced to dilate the canal The following day, assisted by Drs W H and C B Warder and West, he operated The patient was placed in the *lithotomy position*, the vagina held open by retractors, the uterus secured by a ligature through the anterior lip The tumor was adherent over the whole of the posterior surface It was enucleated as far as the finger would reach and finding that the mass was quite large the cervix was

split to the lateral fornix of the vagina on either side and the enucleation completed by the serrated curette After separation of the tumor great difficulty was experienced in its removal The tenaculum and volsella were repeatedly pulled out before the uterus was sufficiently dilated to permit the delivery of the mass A drainage tube was inserted and the cervix closed by three sutures upon either side The tube was removed on the third day There was no rise in temperature until the seventh day when it ran up to 103°, and some cellulitis was found upon the left side This soon subsided under treatment but the patient recovered very slowly She is now well

Dr Montgomery presented a specimen of

HEMATOSALPINX

Mrs K , æt 26 years, married twice, two children by her first husband, missed her menses in May, but had a natural flow June 9 Towards the end of June she felt badly, and so continued until July 11, when she was suddenly taken with violent pain in the right side A homœopathic physician was called, the severe pain soon abated Later he discovered a lump in the inguinal region, this he considered a forming abscess He attended her for four weeks, during which time she was kept in bed by pain in the abdomen and a bearing down or sense of weight, greatly aggravated by the sitting or standing positions Becoming discouraged, she called in Dr E Santee, who asked me to see her in consultation She was a very slight, girlish woman, looking not over sixteen years of age, pale, anæmic, very nervous and anxious Upon the left side of the abdomen could be felt a circular mass, three inches long by one a half in diameter, freely movable, not especially tender Per vaginam was felt a globular mass protruding the posterior wall of the vagina and filling up Douglas' pouch, and apparently continuous with the uterus It was at first supposed that it was a retroverted pregnant uterus More careful examination under ether disclosed fluctuation, and the uterus occupying an anterior position, but slightly enlarged An operation for removal mas advised, though a diagnosis was not certainly determined She entered my private hospital August 24, when, assisted by Drs Warder, Santee and West, the abdomen was opened In raising the tumor on the left side it was slightly ruptured, dark grumous blood escaping Its pedicle was closely connected with the uterus, and examination showed it to be a dilated Fallopian tube Passing the hand behind the uterus, the pelvis was found filled with an encysted mass which proved to be clotted blood This was scooped out by the hand full, the abdomen thoroughly washed out, the left dilated Fallopian tube removed, and the wound closed The temperature before the operation was 100 4°, in the after part of the same day it rose to 100 6°, which was the maximum reached during the convalescence The wound was healed when the dressing was changed at the end of one week The sac, when opened, contained a firm clot of blood, and from its appearance and the history, he believed that an extra uterine or tubal pregnancy had ruptured, causing the hematocele

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, November 9, 1887

The President, J Solis Cohen, M D , in the Chair

Dr E T Bruen reported from his service in the Philadelphia Hospital, cases of

LAPAROTOMY FOR TUBERCULAR PERITONITIS, PULMONARY CAVITY TREATED BY INCISION, ABSCESS OF THE LIVER

Case 1 Abdominal section for chronic tubercular peritonitis —A summary of the prominent features of this case shows the following John B, aged thirty four Admitted to the Philadelphia Hospital May 8, 1887 His first departure from health began June 27, 1880, marked by abdominal pain, swelling of the feet followed in September of the same year His previous history showed a marked constitutional tendency to abscesses He had suffered from a great number of these, including an orchitis, which he considered non-venereal When examined on admission, dry, pleural friction râles were abundantly distributed over the lower zone of each side of the chest, indicating a dry pleurisy, and there were also the physical signs of diffused thickening of the lower portion of the right lung The sputa contained numerous bacilli of tuberculosis The abdomen was very prominent and much distended with fluid in the central portion, but in the hypochondriac regions of each side the course of the colon was defined as a prominent resonant swelling The liquid in the central portions of the abdominal cavity was apparently confined in a species of sac owing to adhesions formed between the peritoneum and the colon, since changing the position of the patient did not change the distribution of the fluid The liver and spleen were also enlarged, and there was marked dulness in the flanks and lumbar regions posteriorly The abdominal distension rapidly increased, uninfluenced by any treatment which was instituted The diagnosis of chronic peritonitis was based partly on the physical signs developed during the examination of the abdomen, viz , its peculiar contour, and the encysted collection of fluid There was no heart disease, and though there was a small ring of albumen in the urine, by Heller's test, there was no evidence of serious renal lesion The associated pulmonary process left little doubt that the nature of the inflammation was tubercular Moreover, there was no history of injury, nor could any evidence be elicited of chronic inflammatory process in the abdominal viscera which might have had an etiological relation with the peritonitis These considerations were especially valuable because the patient's general condition was excellent, color good, and appetite unimpaired On June 18 a gallon of clear serum, with some few shreds of lymph, was withdrawn Unfortunately, paracentesis was necessitated about every three weeks thereafter on account of the rapid accumulation of the fluid, and the dyspnœa occasioned by it The pulmonary process being latent, and the general condition of the patient excellent, laparoto-

my was suggested, and it was thought that possibly by irrigation of the abdominal cavity by means of antiseptic solutions the character of the inflammatory process could be modified and the reaccumulation of fluid prevented On June 28 the operation was accordingly performed by Dr Deaver, assisted by Dr Montgomery On opening the peritoneal cavity a large amount of serum escaped, but no pus was found

The peritoneal surface was much injected and dark red in color, much roughened, and covered with flakes of plastic lymph After drainage, iodoform was dusted freely over the peritoneal surfaces, and the wound closed The patient's subsequent history was unsatisfactory Vomiting was a continuous symptom, and death occurred July 6, nine days after the operation

At the autopsy it was found that an acute attack of peritonitis had followed the operation Extensive adhesions existed along the course of the colon, the diaphragm on the right side was welded to the liver, and on the upper surface extensive adhesions to the pulmonary pleura had been formed The right lower lobe of the lung was infiltrated with nodules of miliary tubercle, the left lung was normal

This case is reported because the number of cases of chronic peritonitis on record is limited in which abdominal section has been performed While tubercular peritonitis is a most serious disease, yet the process may become latent, as is so familiar in tubercular pleurisies in the course of phthisis Just as the gravity of tubercular pleurisy depends upon the pulmonary lesion, so the gravity of tubercular peritonitis depends upon the extent of the frequent antecedent lesions present in the bowels and to the impairment of the functional activity of the digestive tract by the adhesions

The indications for laparotomy would seem, to the writer, to be the same as those which guide us in the inflammations of neighboring serous membranes, the pleura and the pericardium Incision should be avoided in tubercular peritonitis unless the inflam mation is purulent Not only so, but when the tubercular process is present, even paracentesis should be practiced only in those cases in which dyspnœa, from over distension of the serous sacs with fluid, threatens life The danger of operative interference in tubercular inflammation of serous sacs is, that the inflammatory process nearly always becomes purulent

The etiology of the tubercular peritonitis in this case would seem to have been absorption of bacilli from the intestinal canal, possibly from swallowed sputa, particularly as no ulceration of the bowel could be found The lesions in the lung were so inconsiderable, when compared with those of the peritoneal cavity, that the possible channel of abdominal infection was unlikely, viz , the inoculation of the pulmonary lymphatics with those of the diaphragm and abdomen On the other hand, traced from the peritoneal cavity upward, the extensive double pleural process, and the absence of disease of the apex of the right lung, showed that the inflammation probably developed from the peritoneal cavity upward

Case 2 Drainage of a pulmonary cavity —A man, aged twenty-seven years, was found on admission to the hospital to have all the physical signs of a large cavity in the lower lobe of the left lung The physical signs were so unequivocal that the cavity was thought to be very superficial, and to occupy a large portion of the lower left pulmonary lobe The upper lobe was evidently also implicated, the right lung was nearly normal, although at the apex a few moist, crackling râles could be detected

The history of the case was indefinite, but it was gathered that the disease in the lung came on suddenly about six weeks previously, with pneumonic symptoms At date, October 20, the patient suffered very much from cough, expectorated freely pus and nummular sputa, which contained tubercle bacilli The temperature indicated absorption of septic matter, ranging from 100° to 102° The location of the vomica prevented the antiseptic inhalations from really reaching the part, and the patient could not readily empty the cavity by coughing After consultation with two of my colleagues, Drs Curtin and Osler, it was determined to open the cavity and attempt to secure local drainage The physical signs of superficial cavity being most intense at the angle of the left scapula, it was decided to operate at this point Resection of a rib was requisite to obtain working room, as the ribs are close together at this point On October 27 the patient was placed under ether, and Dr Janney, assisted by Dr Porter, removed about one and a half inches of the ninth rib just within a line drawn from the angle of the scapula The pleural surfaces were found to be adherent, and the pleural membrane was slightly thickened It was decided to attempt to enter the cavity with the large needle of an aspirator, and the same was accordingly introduced Although the physical signs had been so pronounced, yet the needle was introduced two inches into the lungs in several directions without entering the cavity The punctures caused no coughing, disturbance of respiration, or, in fact, any inconvenience When the needle was disconnected from the aspirator some little blood escaped, and sufficient air to extinguish a match Finally, a large-sized trocar was introduced in two directions, and it was thought, from the manner in which the front of the instrument moved, that the cavity had been penetrated A small drainage tube was introduced, and the wound dressed after the antiseptic method On the following day the dressings were removed, and it was found that at least an ounce of pus had escaped from the sinus It was decided to enlarge the sinus in which the drainage tube had been placed by dilating it daily with rubber catheters The second day after the operation, while this dilatation was being practiced, suddenly several ounces of pus gushed through the sinus and escaped externally, and thereafter the sucking was heard, so familiar after an empyema has been incised It was manifest that the cavity had, at least, been freely opened, for now injection of fluids into the vomica could be coughed up through the bronchi A blunt probe could be passed seven inches directly into the chest,

and the impulses of the heart could be detected along the probe

There were several points of interest in connection with the details of the operation The first of these was the fact that the cavity was situated at least two inches from the pulmonary pleura Secondly, the first two days the cavity was either not entered, or only a minute opening was created, and yet no damage to the lung occurred, and the temperature fell a degree and a half

The propriety of entering similar cavities with the thermo cautery has been suggested, but when the cavity is situated deeply may not the mode adopted in this case be more simple? Certainly there were no evil effects in the present case I would suggest, therefore, the puncture of cavities in the lung by trocar, and then a small drainage tube can be introduced through the canula, the drainage tube can be exchanged for a large one by dilating the sinus The resection of one or more ribs seems to me an *important feature in the operation for the opening* and drainage of pulmonary cavities, because retraction of the costal wall is facilitated by this measure The general condition of the patient has steadily improved since the operation, and at date his temperature is normal, with greatly reduced cough and betterment of the general strength On November 1, he passed under the care of my colleague, Dr J C Wilson

It is familiar ground to consider the propriety of this operative procedure I feel sure, however, that the most successful treatment of chronic pulmonary inflammations includes rigid antisepsis as one of its cardinal features When cavities have formed their local treatment seems very desirable whenever the strength of the patient at all justifies any hope of success from treatment In regard to the presence of pleural adhesions, these may be counted on whenever the cavity has attained large enough dimensions to allow operative interference to be considered

Case 3 Abscess of the liver —John R , aged 63 years, admitted to hospital October 10, with temperature 102°, and marked symptoms of the typhoid state The bowels were involuntarily moved several times in the twenty-four hours The only other symptom of special importance was severe epigastric pain The patient had been ill for two or three weeks previously, but could give no account of the symptoms On October 16, the liver was very noticeably enlarged, at least an inch in all its boundaries Pain in the epigastrium was a prominent symptom The left lobe of the liver was enlarged, splenic dulness normal, lungs normal The passages from the bowels occurred four or five times daily, and were yellow, watery, and offensive

Temperature October 16, 10 A M , 101°, 6 P M , 102°

17th, 7 A M , $100\frac{3}{5}$°, 11 AM , $103\frac{3}{5}$°
17th, 2 P M , $98\frac{1}{5}$°, 9 P M , 104°
18th, 7 A M , $100\frac{3}{5}$°, 6 P M , 102°
19th, 7 A M , $101\frac{3}{5}$°, 7 P M , 103°
20th, 7 A M , 102°, 7 P M , $101\frac{4}{5}$°
21st, 7 A M , $100\frac{1}{5}$°, 7 P M , $100\frac{1}{5}$°
22d, 7 A M , 100°, 7 P M , $99\frac{3}{5}$°
23d, 7 A M , 100°, 3 P M , 98°

On the 17th 10 grains of antifebrin were given at 11 o'clock, at 2 P M , the temp was 98° Temp at 9 P M , 104° Antefibrin again given, and at 10 o'clock tem $101\frac{3}{5}$° He had a chill at 11 A M , on the 16th, and at 10 A M , on the 17th, neither was followed by sweating The diagnosis of enteric fever was considered and set aside as improbable, on account of the age of the patient, the absence of enlargement of the spleen corresponding to the enlargement of the liver The disorder of the bowels, the pain in the epigastrium, suggested hepatic disease

October 21 The left lobe of the liver was very positively enlarged and tender on pressure The right hepatic lobe was slightly enlarged The right parotid gland was also swollen The evidence of enlargement of the left hepatic lobe with the foregoing symptoms suggested the diagnosis of suppuration Aspiration was determined upon, and the *needle introduced obliquely through the abdominal* wall The needle seemed to slip up over the dome of the liver It was then introduced more perpendicularly, using some pressure, penetrating the abscess, and several ounces of pus were withdrawn On the 22d an exploratory incision was made through the abdominal wall over the point of puncture, and the liver incised Unfortunately, the spot selected for this operation was almost the only square inch of liver which could have been cut without entering the abscess cavity, as will be seen by examining the post-mortem specimen The abscess cavity lay within half an inch of the point of operation The liver was stitched to the abdominal wall, and further explorations would have been made, but death occurred on the following day

Post mortem examination The body was that of a medium sized man very well nourished On opening the abdomen, the left lobe of the liver was found adherent to the abdominal wall This lobe of the liver was enlarged, had a grayish fibroid appearance on the surface, and was closely connected by adhesions with the posterior wall of the stomach On separating the stomach from the liver the abscess was ruptured, and a large quantity of pus escaped There was also a large abscess cavity in the upper and posterior part of the right lobe The tissue shows evidence of recent breaking down, and there is much reddish infiltrated liver tissue in the vicinity There was also a second abscess about the size of an orange, in the right lobe near the suspensory ligament

In the large intestine in the region of the anus, extending two or three inches upward, was a large sloughing mass, with a thick, deeply infiltrated base The edges of this ulcer are greatly thickened Extending above this into the sigmoid flexure, were five large ulcers, and a second large sloughing mass No ulcers were seen on the ascending and transverse colons

The portal vein was free from clots The kidneys were sclerotic, and their cortical portion much diminished Spleen was soft and of normal size Heart, the left ventricle was hypertrophied, aortic

arch dilated and atheromatous -Lungs, œdematous at bases and emphysematous at edges Right parotid gland was enlarged, shows on incision into substance, numerous foci of suppuration The hepatic abscesses are, therefore, undoubtedly embolic, and the lesions in the large intestine were the source of the embolism

It is noteworthy that no hæmorrhage occurred when the liver was incised It also appears to me that the best method of locating a deep abscess after incision of the abdominal wall, would be by passing a trocar into the abscess cavity, and then dilating the sinus This method would obviate the danger of hæmorrhage from the hepatic structure when it may be considered inadvisable to use the thermocautery The recital of this case affords the writer the opportunity to say that he is satisfied that the liver can be safely explored with a moderate sized aspirator needle He has frequently practiced this method in doubtful cases without ever having noticed unpleasant consequences Finally, without entering upon a detailed study of the general diagnostic features of hepatic abscess, it will be observed that the temperature chart of this case shows a wide diurnal variation in the temperature, yet the subnormal temperatures frequently noticed in hepatic abscess were not present, and as antifebrin was used in the treatment, the subsidence of the temperature was probably due to the use of this drug The temperature, therefore, was much more than that of a continued fever, than is commonly noticed in these cases

DR W OSLER said I think that in these cases of abscess of the liver we should, if possible, arrive at an accurate opinion with reference to the etiology of the abscess I saw this case once or twice with Dr Bruen, and I think that if we had made a careful examination of the rectum, the liver would not have been explored, as abscesses resulting from dysenteric processes in the large intestine are almost invariably multiple To explore the liver thoroughly in a case of multiple abscess is a hopeless surgical procedure

With reference to the case of tubercular peritonitis, I may say that these cases frequently come before surgeons and gynecologists for diagnosis In some cases the effusion simulates closely a tumor I do not believe that surgical interference will ever come into vogue in the treatment of this condition, as the general condition of the patient is, as a rule, such as not to warrant surgical interference In the case reported to night, the rapid reaccumulation of the fluid brought in an element which rendered it probable that incision would be of service

DR W H PARISH said I have had no experience in exploring the liver for pus, but I should hesitate a long while before accepting the statement that it is safe to explore an abscess in any organ where it was necessary to pass the needle through the peritoneal cavity If adhesions exist between the two peritoneal surfaces, the exploration may be safe The experience of all abdominal surgeons is that aspiration of a tumor within the abdomen, more particularly of tumors containing pus or irritating fluids, is attended with considerable risk I think that aspiration of an abscess of the liver, where adhesions had not been formed, would be attended with more risk than the aspiration of an ovarian tumor, and the risk attending the latter is not small The usual septic character of the pus of an abscess in the liver, must render aspiration peculiarly hazardous The thrusting of an aseptic needle into healthy liver tissue is, however, doubtless quite safe

DR J B ROBERTS said I scarcely think that tapping of the liver is such a dangerous procedure as would be indicated by the remarks of the last speaker If I had a case of suspected abscess of the liver, I should introduce an aspirating needle in various directions with a great deal of certainty that I should do no harm There would certainly be no harm if an aseptic needle were used and there was no pus The escape of a little aseptic blood into the abdominal cavity is not a serious matter It would be a more serious matter to leave an abscess of any ordinary size undetected

Abdominal section in cases of tubercular peritonitis seems hardly in accordance with our ordinary ideas In the paper to which Dr Bruen has referred, I see that the author has claimed that good results were obtained I can hardly see what good could be expected from it

DR W G PORTER said Some six months ago a patient was admitted to the Presbyterian Hospital There was a considerable collection of fluid in the abdomen, and on palpation a growth could be felt, the exact nature of which we could not determine It was decided to make an exploratory incision On opening the abdomen an extensive tubercular peritonitis was found Since the operation, the woman has remained in about the same condition as previous to it

DR BRUEN said With reference to exploration of the liver, I gave expression to my opinion because I think it desirable to have the experience of those who have punctured the liver Not long ago I saw a case of suspected abscess of the liver, and on three separate occasions I punctured the liver in different directions before I succeeded in obtaining pus Although the abscess was a large one, no harm resulted from the punctures In one case I punctured the liver as often as six times, but failed to find pus This patient recovered

I would reiterate that with aseptic precautions, I consider this a safe thing to do The calibre of the needle should be as small as possible At the same time, the pus is often thick, and it is necessary to employ a needle of fair size Of course, if it was thought that there were a number of abscesses in the liver, we should not think of operating, but in view of the uncertainty which attends the diagnosis, I think it right to give the patient the benefit of the doubt All of the cases of abscess of the liver that I have seen in this city have been pyæmic In one case, the abscess sac was very large, and if drainage had been secured early, temporary benefit at least would have been obtained

CHICAGO MEDICAL SOCIETY

Stated Meeting, October 17, 1887

THE PRESIDENT, W I BIFFIELD, M D, IN THE CHAIR

(*Concluded from page 790*)

DR A H BURR exhibited an

ACEPHALOUS CHILD AT TERM

A lady was taken with labor pains a 7 o'clock this morning, at 9 I was called to see the case, and at 10 this specimen was delivered There is an entire absence of cranial development, the features pretty well developed, but no neck is apparent, and the spine is bifid, commencing with the seventh vertebra, the divided prominences are plainly discernible on the bifurcativus from here to their attachment, apparently to the parietal bones The occipital bone seems to be absent Some of the interesting features in this case were the enormous amount of amniotic fluid I have never seen so much—smallness of the placenta, smallness of the cord, and a little variation in the attachment of the cord to the placenta, its attachment was at the centre, but there seemed to be an adhesion of the cord to the amnion pretty near to the margin of the placenta, and along the course of this adhesion some of the placental veins passed into the cord I delivered this lady nearly three years ago of a very healthy and well developed boy, with exception that he has hypospadia She had given birth prematurely to two others that were similarly deformed

Stated Meeting, November 7, 1887

THE PRESIDENT IN THE CHAIR

DR JAMES H ETHERIDGE read a paper on

VAGINAL HYSTERECTOMY

(See page 806)

DR C T PARKES I am very much pleased with this paper, in that it introduces a method of controlling hæmorrhage that has been satisfactory to me a good many times We are indebted to Péan, of Paris, for this method He depends upon it on all occasions and in all operations It is not an unusual thing to find a wound that he has made containing a dozen of these forceps He never uses a drainage tube After seeing it done by him, I have resorted to the use of the forceps as a means of hæmastasis in all operations where it was difficult to apply a ligature, and especially in removal of carcinoma of the rectum Any one who has performed that operation knows how difficult it is to apply a ligature that can be trusted, high up in a wound so small as that made in the removal of a carcinoma of the rectum And on several occasions I have left half a dozen forceps, removing them in twenty four hours, without subsequent trouble It saves a great deal of time, and is perfectly reliable I do not think, it is necessary, on all occasions, to leave the forceps on forty-eight hours I think that after squeezing with the large jawed forceps for twenty four hours, there is scarcely any danger of hemorrhage from a vessel the size of those that are included in it, and by diminishing the time of the retention of the forceps you reduce the danger of necrosis of the tissue contained in the forceps Another point, I don't see the necessity of turning the uterus over, thus endangering the entrance of diseased tissue into the peritoneal cavity The posterior wall is uncovered, the broad ligaments are exposed, and what is the use of turning the uterus over? These forceps will reach the top of it, and they will include the broad ligaments on either side, and they can be applied just as well with the uterus in position as if it was turned over There is great necessity of keeping close to the uterus with the forceps I think there is more danger with the use of the forceps, in including the ureter, than we are aware of, and if the operation is done where there is any probability of recovery, it does not do any harm to keep well up to the uterus If the tissue is diseased beyond that point you might as well let the patient alone

DR D T NELSON I wish to quote a word from Martin, of Berlin, spoken before the International Congress, where this subject was discussed quite fully He advocates the operation strongly, and made this important point, which I think, was not too much emphasized by the reader of the paper, that the operation is not justifiable when the uterus is not movable When the tissues above and about the uterus have become involved by the diseased condition, then the operation should not be done Martin's later operations have been only upon this class of cases, and consequently the promise of success—permanent cure—has been far greater than it would otherwise be

FOREIGN CORRESPONDENCE

LETTER FROM VIENNA

(FROM OUR OWN CORRESPONDENT)

Sixth International Congress for Hygiene and Demography, in Vienna

The third Section discussed in its first session, on Tuesday, September 27, the report presented by Dr Hueppe, of Wiesbaden, viz "The Connection between the Supply with Drinking-water and the Origin and Spread of Infectious Diseases, and the consequences to be derived therefrom with reference to Hygiene" The Section was presided over by Prof Virchow, of Berlin, and Prof Gaffky, of the same city, held the place of a Vice-President The reporter, Dr Hueppe, directed the attention to the printed report he had presented, and remarked that though there were no positive proofs for the importance of the water-supply with reference to the epidemic spread of typhoid fever and cholera, our experience and the general considerations made it none the less probable that the drinking water indeed played a part in the spread of those infectious dis-

Scarlatina as a Prophylactic It had long been known, he said, that foot and mouth disease may be communicated to the human subject, either through the agency of milk from animals suffering from the disease or by the accidental introduction of virus into open wounds Among the characteristics which it presented in man were glandular enlargements, vesicles in the mouth and upon the hands and feet, and, in cases, a scarlatinal eruption on different parts of the body This was the case with Herting and others who purposely contracted the disease by drinking milk from infected cows

He then gave some account of the sudden and severe epidemic of sore throat which occurred in Dover, England, in 1884, and attacked the inmates of the best houses in the place, and said that it was conclusively proved that the outbreak originated from milk obtained from cows suffering with foot and mouth disease In the majority of the cases the two principal symptoms were inflammatory sore throat and enlarged cervical gland, while in many instances vesicles were also noted The sequelæ in general resembled those of scarlet fever An investigation of 182 of the cases, made two years after the outbreak, showed the following points

1 None of the patients had since had scarlatina

2 Members of families who had previously had scarlatina as a rule escaped the epidemic, while those who had not had scarlatina were generally attacked

3 Sixteen of the patients had already had scarlatina

4 Four of them were very mild cases

5 Two of them had had scarlatina when they were very young

6 In ten cases it was doubtful whether the patients had had scarlatina or not

After directing attention to the significance of these facts Dr Stickler related the histories of three cases in which he inoculated children with virus from milch cows and subsequently exposed them to the contagion of scarlet fever The first was a boy 8 years of age, who after he had entirely recovered from the effects of the inoculation, was taken to the bedside of a scarlet-fever patient and made to inhale the breath of the latter and place his head upon the pillow and by him Yet, notwithstanding this experience, the boy did not develop scarlet fever The second was a child 4 years of age, in whom the inoculation produced much greater constitutional disturbance than in the preceding case The throat and mouth became sore, the temperature rose to 103°, and there was a scarlatina eruption followed by desquamation This child was afterwards directly exposed to the infection of scarlet fever in the same way, and did not contract the disease The third child inoculated was a boy ten years old, and although during the three years that had elapsed since he had been inoculated he had more than once been exposed to the risk of scarlet fever, he had thus far escaped having it

While foot and mouth disease, Dr Stickler said, was essentially the same in man as in animals, there were some points of difference, and he now proceeded to describe in detail the symptoms met with in the latter There were four marked stages its clinical history in animals, viz fever, eruption, desiccation and desquamation In milch cows the flow of milk became nearly suppressed, while the milk secreted was of a yellow color and readily coagulated on boiling or even when exposed to a moderate degree of heat There were vesicles in the mouth and throat, and unhealthy ulcers and erosions were sometimes left after them Thomas had stated that scarlet fever was the only disease in which the mucous membrane could be torn away in considerable pieces, but he was probably not aware that this was also the case in foot and mouth disease Repeated attacks of the affection in the same animal were supposed to be rare, but authorities differed very greatly in regard to this point

Klein, he went on to say, had discovered what he believed to be the germ of foot and mouth disease, and stated that it could not be distinguished from the germ met with in the disease, caused by milk, at Henden, and was unquestionably scarlatina In order to test the transmissibility of scarlatina from man to the lower animals, Dr Stickler inoculated two colts by injecting virus into the jugular vein, and also giving them mucus from the throats and mouths of scarlet-fever patients to swallow In one colt the temperature went up to 103°, and in both there was sore throat, redness of the mucous membrane, cough and difficulty of deglutition In one of the cases there also resulted desquamation Having repeated these experiments in a large number of other animals, he was convinced that it was possible to inoculate the lower animals with scarlatina

In inoculating human beings with virus from animals thus treated the lesion was found to be a mild one, and he believed that this virus could be used in such a way as to prevent scarlet fever subsequently Five years ago he had inoculated twelve cases in this way with good results Out of thirteen other children inoculated, who were already exposed to the infection of scarlet fever at the time, five escaped the disease entirely, while eight were attacked with it None of these cases were severe, however, and the question arose whether the severity of the attack had not been mitigated by the inoculation In conclusion, he stated that he hoped to pursue still further the investigations in which he was engaged

In the discussion which followed the paper Professor Law, of Cornell University, said that as regards the prophylactic power of foot and mouth disease against scarlet fever in the human subject, he was still skeptical In Great Britain there are frequent outbreaks of the disease, which affected not only the cattle but the people coming in contact with them, and he thought that if foot and mouth disease was a protection against scarlatina, the latter ought to be a much less common affection there than in this country, where epizootic apththa, or foot and mouth disease, was almost unknown Such, however, was not the case, as the statistics showed that during the last five years there had been no less than 90,000 deaths from scarlatina in Great Britain Then, again, an attack of foot and mouth disease conferred a very limited, if any, immunity from subsequent attacks,

and he had known it to recur within six months in the same animal Recurrence of the disease was very common in his experience, and he would, therefore, hardly suppose that inoculation with it would confer immunity from scarlatina for any length of time, if at all Still, it did certainly follow that the immunity conferred by foot and mouth disease might not be more extended in a race less susceptible to its influence than the bovine

As regards foot and mouth disease, Professor Law said he would strongly urge that the investigation should be carried on on the other side of the Atlantic, as he thought it would be a very serious matter if that affection should be introduced by this means among American cattle, and he had no doubt that there would be a general outcry among the cattlemen if it were known that experiments were being made with the virus of the disease in this country Then, as regards scarlatina, he said he feared that if the virus of this disease were employed for making inoculations it would only disseminate scarlatina more widely While he had great respect for the ability and achievements of Pasteur, he could not but believe that he had increased the spread of anthrax by scattering broadcast anthrax virus, for he was convinced that a weakened virus might under certain conditions be rendered potent and dangerous In the same way, he believed that rabies would only be increased by the dissemination of his attenuated virus of that disease, and he understood it to be a fact there had been more rabies among the dogs in England since the discovery of Pasteur than ever before These considerations, in his opinion, condemned the methods proposed by Dr Stickler for the prophylaxis of scarlet fever

Among the other speakers was Dr J Louis Smith, who said that since the time of Jenner the hope had been awakened that some of the other fatal infectious diseases, and especially scarlet fever, might be prevented, as small pox had been, by the substitution of a milder and modified disease derived from the lower animals As regards scarlet fever, two propositions of great interest and importance had arisen *First* Is there a disease in the bovine race which is a true scarlet fever, or which communicates genuine scarlet fever to man? and, *Second* If there is such a disease does it produce a mild and modified form of scarlet fever in man? Many instances had been recorded in the last five or six years in which epidemics of scarlet fever had arisen from the use of milk furnished by healthy cows and infected with the scarlatinous germ after the milking, but in the St Marylebone and Henden epidemics, occurring two years ago, the outbreak of scarlet fever appeared to be clearly traced to diseased cows The point to which he wished to call attention was this The sickness of the cows was mild, not appreciably impairing their appetite, or diminishing their milk, but the disease which the use of the imported milk produced was described as an intense outbreak of scarlet fever Instead of a mild disease being propagated from the cow for which we are looking, the reverse had occurred A mild form of the disease in the cow produced a severe one in man, so that it appeared from the history of this epidemic that by inoculating with the bovine scarlatinous virus we might produce severe and fatal epidemics, instead of a mild and modified form of the disease

Dr McLean, one of the veterinaries present, contended that while the epidemics alluded to had undoubtedly originated from milk, it had by no means been proven that the disease came from the cows themselves, and expressed the opinion that there was no such thing as bovine scarlatina except possibly in cases where scarlatina was produced in the cow by direct inoculation with scarlatinal virus from the human subject

In closing the discussion Dr Stickler said that if he produced only a slight and harmless attack of scarlatina by his inoculations he could see no objection to the use of scarlatina virus for this purpose, and when the terrible aspects of the unmodified disease are taken into consideration the extreme importance of securing some such means of protection was evident As to the disease from which the Henden cows suffered, it had, he thought, been clearly demonstrated that it was nothing else than scarlatina, since it was precisely the same affection as was ordinarily produced in cows by the inoculation of scarlatinal virus from the human subject

The beautiful new building of the New York Cancer Hospital, on Eighth Ave and 105th street, opposite Central Park, which is largely the gift of Mr and Mrs John Jacob Astor and the late Mrs General Cullom, was formally opened with appropriate ceremonies on the 6th of December On this occasion the principal address was made by Dr Fordyce Barker, and addresses were also made by Dr Wm H Draper, the Rev Dr John Hall and John E Parsons, Esq , President of the Board of Trustees The present structure, which is admirably adapted in every way for the purpose designed, is for female patients alone, of which it will accommodate about eighty, and will constitute only a single pavilion of the institution when the entire hospital, as it is now contemplated, is completed As was stated in this correspondence when it was first announced that the building was to be erected, it is unfortunate that the efforts of those having the matter in charge should not have been exerted in behalf of the New York Skin and Cancer Hospital, an institution of prior origin and one which embraces the same objects in its scope, since by this division of interests there is naturally a considerable waste of energy and resources which ought properly to have been concentrated upon a single charity of the kind

At a recent meeting of the Clinical Society Dr McKim reported a successful case of laparo elytrotomy for deformed pelvis The child was born dead, but the mother, after a pretty hard struggle, in which oxygen gas was used with good effect in supporting the flagging powers of nature, recovered In this connection it may be noted that Dr Wm T Lusk is winning splendid laurels for himself by his Cæsarean section by the modified Sanger method, having had three successful cases within a year, two of which have occurred during the past autumn In the first two cases both mother and child were saved,

but in the third, which is quite recent, the child unfortunately died of tetanus

In the death of Dr Theodore R Varick, the eminent surgeon, of Jersey City, the New York State and County Medical Associations have lost a most devoted friend and highly valued contributor to their scientific work In 1885 he read an able paper on the use of hot water in the treatment of wounds, in which remarkable results with this method were reported, before the County Association, of which he was afterwards made a non-resident member, and at the meeting of the State Association in 1886 he took a conspicuous part inthe discussion on the treatment of gunshot wounds of the intestines which constituted the most noticeable feature of the session

P B P

NECROLOGY.

MARTIN ROOT, JR

Martin Root, Jr, M D, of Byfield, Mass, the fourth son and tenth child of Martin and Lucinda (Clary) Root, was born July 8, 1802, at Montague, Mass, which was his home through boyhood and early manhood He died at his residence in Byfield, October 28, 1880

His rapid growth out of boyhood—some six inches in seven months—caused an unhealthy development of height of which he was so ashamed that he used to sit at his studies bending over as much as possible, endeavoring to hide his height, until hæmorrhage of the lungs compelled him to desist His physician advised a sensible hygienic treatment of open air exercise, and he also wore the old fashioned steel busk to help maintain an erect position

His literary education was the common school of his home, followed, when about 22, by one term at Amherst Academy Then he taught a district school for one winter in Granby, Mass, after which he commenced the reading of medicine with Dr Sellon, a popular and successful botanic physician of Amherst His lecture courses were at the Vermont Academy of Medicine, connected with Middlebury College, Vt, but located at Castleton, Vt, during the fall terms of 1824 and 1825, with a private supplementary course in Anatomy at Albany, N Y, under the tuition of Dr Alden March, in the winters of each of these years, and graduating as an M D, at Middlebury, in the summer of 1826

In the autumn of 1826 he attended a post-graduate course at the Berkshire Medical Institution, located at Pittsfield, Mass, and connected with Williams College

The names of William Tully, Amos Eaton, Chester Dewey and John De la Matter appear among his instructors during these courses

His life seemed destined to be a short one, but the preventive training of Dr Sellon apparently held at bay the further progress of the disease, and enabled him to return home at the close of his medical studies in readiness for the opening of his life work

One day he heard allusion made to a place called Byfield, whose physician, Dr Parker Cleveland, had died about a year before, after an active medical service of fifty years, and in March, 1828, he set out upon an exploring tour He found it difficult to learn anything about the place, though one landlord told him that he had heard of a Byfield breed of hogs of considerable local celebrity But at last Dr Root reached the place The prospect seemed satisfactory in its outlook, especially as Dummer Academy was located there, and a cotton factory, the first in New England, was at work at Parker River Falls, and he took up his abode and his work for life

On March 2, 1829, he married Jerusha Barbour, daughter of James and Dorcas (Doane) Barbour, of Bridport, Vt, who was at that time living with her brother, Rev Isaac R Barbour, the minister of Byfield Parish A family of seven children filled the home, of whom five are now living The youngest child, Richmond Barbour, is a physician in Georgetown, Mass, and a member of the Massachusetts Medical Society

After some ten years of practice his health began to fail, compelling him to take a vacation of six weeks, which was spent in a carriage journey to the Lake Champlain Valley of Vermont This little rest seemed to renew his vigor, and he never again left his work for any length of time

He became a member of the Massachusetts Medical Society in 1834, and at the second annual meeting of the Essex North District Medical Society he was one of the three selected for return to the Recording Secretary of the Massachusetts Medical Society as Councillors In July, 1843, he was chosen Secretary *pro tem* of this District Society, and his name then first appears officially affixed to the record of this meeting At the next annual meeting he was chosen Permanent Secretary From the official recognition of his death by this Society we quote the following allusion to his work as Secretary

"From this time on his name is signed to the records of every meeting, with a single exception, up to January 29, 1874, a period of over thirty years, and only once during all this time was he absent

"At the twelfth annual meeting the office of Treasurer was joined to that of Secretary, and from that time he was in charge of the finances of the Society At the annual meeting of May 6, 1874, he declined a reelection on account of the failure of his eyesight, connected with the other infirmities of age Dr Garland, of Lawrence, offered the following resolution, which was unanimously adopted

"'*Resolved*, That Dr Martin Root, by his untiring industry and faithfulness as Secretary and Treasurer of this Society for a period of thirty one years, has secured our entire confidence and highest esteem, and as a slight testimonial of this feeling we authorize the Treasurer to pay over to him the sum of fifty dollars for his sole use'

"A small tribute, surely, for such long and faithful service, but bestowed with the most cordial goodwill From this time he was seldom present at our meetings"

For fifty-two years he engaged in the active duties of his profession, until about four years before his

death, when a gradually failing eyesight ended in a year or two in almost complete blindness, until he passed out of this darkness into the light He became a member of the American Medical Association in 1855 He attended in 1860, 1864 and 1865

There is little in a life spent in the sequestered, unheralded Parish of Byfield which can interest the public at large, even though that life was measured by a half century of most honorable professional work Cautious in his treatment of disease, he had few errors to try to make right Conservative in his thinking, he yet led two Harvard medical students to say that the "old doctor" taught them a lesson of progress even in old age And more than all else in his character, the moving power of every thought, word and act was that of supreme loyalty to the Christ who to him was all in all

His life is embalmed in the memory of the families for whom he was the "beloved physician" for fifty years—whose children entered life with his attendance, whose sick were restored to health by his untiringly faithful care, and whose dead ones his skill could not save M N R

ALMON S BONSTEEL, M D

Dr Bonsteel, a prominent physician of Corry, Pa, died of diphtheria on October 22, at 49 years He was born in Ellicottville, N Y, July 17, 1838 He was graduated from Bellevue Hospital Medical College He settled in Corry in the spring of 1872, and was engaged in active practice until he fell a sacrifice to the duties of his profession He was a member of the County and State Medical Societies, and of the American Medical Association He was an accomplished, energetic, and unassuming physician, and an upright citizen

BOOK REVIEWS

A System of Gynecology By American Authors Edited by Matthew D Mann, A M, M D, Professor of Obstetrics and Gynecology in the Medical Department of the University of Buffalo, N Y Volume I Illustrated with 3 colored plates and 201 engravings on wood 8vo, pp xii–789 Philadelphia Lea Brothers & Co 1887

PRELIMINARY NOTICE

Notwithstanding the number of works on gynecology, and the recent rich development of gynecological literature the profession in this country has now eagerly looked forward to the appearance of this, the first volume of the System of Gynecology by American Authors, which was announced as forthcoming several years ago The place, the need, for such a work need not be discussed, being apparent "Gynecology has now grown to an extent which requires for its thorough treatment this cooperation of representative men, and it is eminently fitting that the science which is in so great a degree of American origin should be thus presented by American practitioners"

The opening chapter of this volume is a "Historical Sketch of American Gynecology," by Dr Edward W Jenks, of Detroit The remaining fourteen chapters, with the names of the writers are as follows The Development of the Female Genitals, by Henry J Garrigues, Anatomy of the Female Pelvic Organs, by Henry C Coe, Malformations of the Female Genitals, by Henry J Garrigues, Gynecological Diagnosis, by Egbert H Grandin, General Consideration of Gynecological Surgery, by E C Dudley, General Therapeutics, by Alexander J C Skene, Electricity in Gynecology, by Alphonso D Rockwell, Menstruation, and its Disorders, by W Gill Wylie, Sterility, by A Reeves Jackson, Diseases of the Vulva, by Matthew D Mann, Inflammatory Affections of the Uterus, by C D Palmer, Subinvolution of the Vagina and Uterus, by Thaddeus A Reamy, Periuterine Inflammation, by Richard B Maury, and Pelvic Hæmatocele and Hæmatomata, by Ely Van de Warker

The volume is well indexed As usual, the publishers have done their part of the work in a way to which no exception can be taken

ASSOCIATION ITEMS

MALARIA AND THE CAUSATION OF FEVERS

To the members of the Committee on State Medicine, and to others interested in Public Health subjects

Gentlemen—As Chairman of the Committee on State Medicine, of the American Medical Association, and as one greatly interested in sanitary progress, permit me to offer a few suggestions designed to systematize the work of our Section at the next meeting of the Association, in Cincinnati, Ohio, the second Tuesday in May, 1888

It would seem that a stronger impulse can be given if, instead of scattering over the entire field of the medical sciences, many of us concentrate our efforts upon the same subject

As the first requisite for the prevention of sickness or of deaths is a knowledge of the *causes* of the sickness or of the deaths, and as the causation of disease may be most appropriately studied in an association of physicians, I recommend that an effort be made to contribute for the advancement of our profession, for the use of non medical sanitarians, and for the benefit of humanity in general, so much as is practicable of well systematized facts, and considerations bearing upon the "Causation of Disease"

To still further concentrate our energies, I recommend that the special topics for this meeting be "*Malaria, and the Causation of Fevers*" One reason for this is that, even in the Northern State in which I live, intermittent fever (though causing few deaths), is reported as causing more sickness than does any other disease whatever

It would be of interest to know, for each State

1 The proportion of all sickness, that, by reputable practicing physicians, is attributed to malaria

2 Just what groups of signs and symptoms are accepted as evidence of the influence of malaria

3 To what extent sickness attributed to malaria is increasing or decreasing

4 What are the meteorological and other conditions coincident with the increase or decrease of malarial diseases?

5 What facts are there bearing upon the question? What is malaria?

6 What evidence is there for, or against a malarial germ?

Probably it will conduce to the advancement of our knowledge, if the member of this Committee in each State will collect facts, and, at the coming meeting report, or have some one report for his State, on the topics I have suggested, and upon any other subject which he may think important

Members of the Association that are pathologists, physiologists, bacteriologists, or chemists, will, I think, be especially welcomed if each, from his own standpoint, will discuss that part of the subject relative to the "Causation of Fevers" Statisticians may well give us the evidence that they are able to bring bearing on the topics suggested, and the busy practitioners that have the best opportunities for observing these diseases, will be expected to contribute their share

In case you prepare a paper, report, or for a discussion, I trust you will remember to conform to the rules of the Association, and be sure to inform the Secretary of the Section, S T ARMSTRONG, M D, Marine Hospital Service, New York City, concerning the title, and the time required, in order that the programme may provide for its presentation

It will give me pleasure to hear from you on the subject Very respectfully,

HENRY B BAKER,

Ch'n Section on State Medicine, Am Med Ass'n

Lansing, Michigan, December, 1887

MISCELLANEOUS.

SMALL SOCIAL VICES —A correspondent very sensibly directs attention to the influence exercised by some of the niceties of modern life upon the physical condition of young women at the present day Without adverting to such grave excesses as the free use of alcohol and of toxic remedies, he instances incessant tea drinking, sipping eau de cologne, and addiction to sensational novel reading as examples of the prevailing spirit of self indulgence There is considerable force in his observation that we may be disappointed in the result if girls, who have in these and similar matters been allowed to regard their wish as their ideal, should at any time have to resume the responsibilities of motherhood The practices to which he refers are, happily, counteracted in many cases by a native strength of mind and body, or by other habits of a more wholesome character Still, it must be allowed that they are not in themselves conducive, but rather injurious, to health They are part of a general tendency to luxurious living, which is not peculiar to one people, century, or sex, and to which we, as a prosperous commercial nation, have too readily become subject The means of correction are not to be found in Pharmacopœias or in regulations as to the safest methods of indulging the petty cravings of selfish desire The real remedy will be found in a return to simpler or less artificial usages, and in the increasing recognition of the value of some guiding purpose, even in the leisure and the diversions of our lives A general understanding of sanitary principles would also assuredly do much to assist the formation of a just estimate by the general public, of what is, and what is not, calculated to favor the healthy growth of mind and body These principles are now happily becoming better and more widely appreciated than formerly The evils associated with such vices of civilization as the social customs we have referred to stand, therefore, a fair chance of great limitation, if not of extirpation, when the verdict of common sense thus instructed will have been pronounced upon them —*Lancet*, Nov 26, 1887

A JUST JUDGE ON PATENT MEDICINES —Mr Justice Kay, in the Chancery Division, in the case of C A Vogeler & Co *v* Middleton, was asked to restrain the defendants from advertising and selling an oil as St Joseph's Oil, as being an infringement of the plaintiff's trade mark, and calculated to deceive the public Mr Justice Kay said that both plaintiffs and defendants were venders of quack medicines, which were largely advertised to heal all manner of external injuries He declined to rule that the use of any saint's name in the calendar was an infringement of the plaintiff's trade mark But lest either party should use his judgment as an advertisement, he hoped they would add that no one should employ either preparation except under medical advice The judge's counsel is excellent It is too much to expect that the parties to the suit will publish it But we gladly give it publicity and praise —*Lancet*, Nov 19, 1887

SALOL IN TYPHOID FEVER —Salol, in gr iij doses, every 3 hours, in typhoid fever, is highly recommended

---

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM DECEMBER 10, 1887, TO DECEMBER 16 1887

Major G M Sternberg, Surgeon, assigned to duty as attending surgeon and examiner of recruits at Baltimore, Md

Major P J A Cleary, Surgeon, assigned to duty at Ft Wingate, N M

First Lieut C L G Anderson, Asst Surgeon, assigned to duty at Ft McDowell, Ariz

Capt A W Taylor, Asst Surgeon, assigned to duty at Ft Robinson, Neb

Capt A H Appel, Asst Surgeon, assigned to duty at Camp at Highwood, Ill, relieving Asst Surgeon H O Perley

Capt H O Perley, Asst Surgeon, will rejoin his proper station (Ft Wayne, Mich) S O 285, A G O, December 8, 1887

First Lieut W B Bamster, Asst Surgeon, ordered to proceed at once from Ft Lowell, Ariz, to Ft Wingate, N M, and report to the commanding officer for duty S O 128, Dept Ariz, December 1, 1887

First Lieut J M Cabell, Asst Surgeon, ordered for duty at Ft Niobrara, Neb S O 286, A G O, December 9, 1887

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING DECEMBER 17, 1887

Medical Inspector A Hudson, ordered to the "Trenton"

Medical Inspector N L Bates, detached from the "Trenton," and placed on waiting orders

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDING DECEMBER 19, 1887

Surgeon R D Murray, granted leave of absence for fourteen days December 8, 1887

Surgeon J M Gassaway, granted leave of absence for fifteen days, to take effect when relieved December 17, 1887

Surgeon Fairfax Irwin, relieved from duty as Acting Chief Clerk, Office Supervising Surgeon General, and to wait orders

P A Surgeon S D Brooks, granted leave of absence for thirty days, to take effect when relieved December 15, 1887

Asst Surgeon W P McIntosh, to proceed to Wilmington, N C, for temporary duty December 13, 1887

Asst Surgeon G M Magruder, granted leave of absence for twenty one days December 19, 1887

Asst Surgeon P M Carrington, ordered to examination for promotion December 14, 1887

HOSPITAL NOTES.

WOMAN'S HOSPITAL, INDIANAPOLIS

A COLECTOMY, WITH NEW USE OF BERGEON'S METHOD

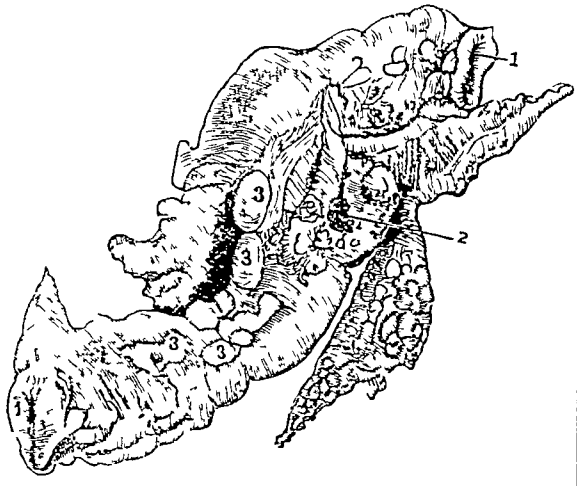
(Reported from the Service of Joseph Eastman, M D , by John F Barnhill)

Mrs B , under the care of T C Donnell, M D , Franklin, Ind , aged 20, mother of child 8 months old, referred to Dr Eastman in Sept , 1887 History of low general health for many months After birth of child obstinate constipation, resulting in almost complete obstruction Relieved only by gr ½ ext bella donna Noticed enlargement in left inguinal region

Examination *per vaginam* right ovary enlarged and tender Iliac enlargement seemed to have connection with uterus Over abdomen the tumor could be only indefinitely mapped out

Operation, September 27 — Incision in median line Ovaries examined Right one size of hen's egg, and was removed, pale, and fibroid in appearance Left ovary healthy Enlargement in left iliac fossa elevated from pelvic floor and brought higher into wound, was found to be a pathological condition of descending colon immediately above sigmoid flexure

Removal of diseased portion determined upon Section of gut made 2 inches above, and 2 inches below morbid boundary line No portion of mesentery removed Portion exsected, 8 inches long with appearance shown in figure, drawn by myself



1, 1 opening of superior and inferior ends 2 perforation by finger into calibre of gut, made by lifting it up it being in advanced state of degeneration 3 3 3 3 secondary growths from main tumor The wing like appendages of like character

Distal ends of gut approximated by Lembert's sutures No 10, iron dyed silk sutures were used, each suture passing deep, through muscle and submucosa of intestinal wall The operator had not then read the very able article of Dr Halsted, (See *American Journal Medical Sciences*, October, 1887 "Circular Suture of Intestine," by Wm S Halsted, M D , New York), but from anatomical knowledge of intestinal coats, knew the value of a suture, including the sub mucosa, which is the strength of the intestine Sutures taken one eighth inch apart around the whole intestinal circumference When the parts seemed well approximated, it occurred to the operator to test the work Bergeon's apparatus for making sulphuretted hydrogen gas being at hand, he ordered a bag of the gas generated, injecting a quantity *per rectum* Some escaped at the wound as could be easily determined by its odor More sutures were taken, and the gas test reapplied A small quantity again escaped, and other stitches were taken, gas now failed to escape, proving the edges well approximated

Glass drainage tube left in abdominal cavity Little shock followed Highest temperature at any time 99⅗° F Bowels acted on fourth day, again on fifth, and afterwards comparatively regular Drainage tube removed on fifth day In ten days patient sufficiently recovered to walk about the room, and in five weeks to return home So favorable seemed the convalesence, that the diagnosis of carcinoma, which had first been made, was now somewhat doubted by some Bowels acted perfectly well for eight weeks, when she ceased to do well and Dr Eastman was asked to visit her She was vomiting, exhausted, with abdominal cavity filled with ascitic fluid Drew off the fluid and two days later made incision into abdomen to learn more of condition The site of exsected bowel was normal From the pedicle of the ovary removed, sprang a vegetating mass as large as the first, which left no doubt as to its being carcinoma (Microscopic examination by Dr Rachael Hickey, of Chicago, showed the specimen to be carcinoma, of cylindrical celled variety)

Patient died four days later No autopsy Antemortem examination obviated its necessity, since the sutured bowel, mesentery, uterus and ovarian pedicle with its growth, were then examined sufficiently to warrant the statement that patient died from the disease extending, and that recovery from the operation was perfect

MEDICAL PROGRESS.

SUPPURATIVE PERITONITIS, OPENING, WASHING, AND SPONGING THE PERITONEUM, RECOVERY.—At the meeting of the Clinical Society of London, on October 28, MR RICHARD BARWELL read notes of this case The man, æt 42, accustomed to drink a good deal, was admitted into Charing Cross Hospital June 24, 1887 Six days previously he fell and struck the left lower part of the abdomen, but seemed very little hurt Five days afterwards he, in stooping, felt severe pain in the lower part of the abdomen, he vomited and passed a little very dark colored urine (Absence or presence of blood could not be verified) He went to bed, his abdomen swelled, he passed very little urine, vomited after, and sometimes without, taking food On admission he was placed in a warm bath, while in it he passed what may, he thinks, have amounted to a wine-glassful of urine At 2 P M Mr Barwell found him with pinched, anxious countenance, pulse small, hard, and quick, and temperature 100 4°, dry skin, tongue somewhat coated, vomiting, abdomen slightly tender, save in left iliac region, much swollen, very tympanitic quite down to the pubes, tapping it produced a peculiar thrill not like that of flatulence A No 12 catheter brought away no urine, even though pressed far back, but the instrument when withdrawn was full of urine deeply stained with blood June 25 On three occasions 10 ounces of urine had been passed, at first with blood, the last sample free of blood, but slightly albuminous, specific gravity 1022, temperature 89°, pulse 130, abdomen more distended It being evident that the man had a bad type of acute peritonitis, Mr Barwell opened the abdomen in the middle line below the umbilicus A large quantity of gas, not of feculent odor, escaped No rupture of any viscus was found, but in its lower part the peritoneum contained a quantity of thick pus There were no adhesions, parts of the intestines were congested, and the membrane was somewhat thickened Three sponges passed into the lower part of the cavity were withdrawn covered with tenacious flocculent pus A smooth nozzled glass funnel was then deeply introduced, and the part of the cavity washed out with 10 pints of distilled water, temperature 99°, bringing away quantities of pus and floccuh After sponging, a second smaller washing and sponging was directed to the upper part The abdomen was then sewn close without any drain The whole operation, including the anæsthetic and dressing, lasted an hour June 26 During the night and day the patient frequently vomited a brown fluid with darker concreta, pulse rather fuller, 110, abdomen scarcely distended, and tender only in immediate neighborhood of the wound He was lying flat, save for a small pillow under the knees, said he was quite well, and wanted to go home July 28 The vomiting slowly decreased during the night, the bowels acted rather copiously four times The vomiting ceased and all symptoms passed rapidly away The rest of the history was that of rapid convalescence, the man being very importunate in requesting to be discharged In his remarks Mr Barwell, referring to a paper by Mr Hancock, claimed for Charing Cross Hospital the first conception of the idea of opening the peritoneum for acute peritonitis (*Lancet*, 1848, "Meeting of Medical Society") He also pointed out that this operation had been performed fourteen times, though the operator had not always known what was the precise nature of the case, and the circumstances had been very various, ulcers or rupture of some part of the intestinal tract, or of an ovarian cyst He emphasized the impossibility of draining the lower part of the peritoneum through a wound in the front of the abdomen, and advised that no drainage-tube should be inserted immediately after operation, but that if distension recurred, to remove the lower stitches and permit escape The presence of a tube, which could not in that position act as a drain, might be injurious rather than beneficial In the female, drainage *per vaginam* would probably be the most valuable treatment as the best wash, since disinfectant lotions, strong enough to act as germicides, could not be brought into contact with any large surface of the peritoneum without injurious effects, local, systemic, or both —*British Medical Journal*, November 5, 1887

NITROGLYCERINE IN NEPHRITIS AND URÆMIA — DR S A LENTOVSKY, of the Cronstadt Marine Hospital, employed nitroglycerine (in tabloids containing each 1–100th of a grain of the drug) and hot water baths in four cases, three of which are given with minute details In two of the patients the daily amount of urine rapidly increased, while albuminuria and dropsy disappeared, and the patient's subjective feeling and general state strikingly improved In a third case the improvement was but fleeting, the patient dying after a short stay at the hospital The *post mortem* examination showed that he had not suffered from nephritis, but from an extensive amyloid degeneration of the kidneys and spleen The remaining case illustrates the beneficial action of nitroglycerine on uræmic symptoms The patient, a girl of 15, was brought in almost unconscious state, with general convulsions, frequent vomiting (the ejected matter smelling of urine), extensive dropsy, stertorous frequent breathing, and small pulse Nitroglycerine and hot baths having been at once ordered, on the next day the girl was able to sit up in her bed, ate with appetite, and generally felt comparatively well —*London Medical Record*, Aug 15, 1887

THE ALKALINITY OF THE BLOOD IN CERTAIN DISEASES —VON JAKSCH, of Graz, concludes that

1 Fever lessens, in greater or less degree, the alkalinity of the blood

2 This lessened alkalinity is a constant symptom in uræmia

3 Diseases of the liver, in which destruction of the parenchyma occurs, produce this condition

4 Leukæmia, pernicious anæmia, and chlorosis lessen the alkalinity of the bood

5 Poisoning with carbon dioxide produces this result also —*Zeitschrift fur klinische Medicin*, Band 13, Heft 3 and 4

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO, ILLINOIS

SATURDAY, DECEMBER 31, 1887

CLOSE OF VOLUME IX

The present number completes the ninth volume of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and four and one half years of its publication In complying with a By law of the Association which requires the publication of the full list of permanent members of the Association every three years, we have given the list in this number as furnished by the Secretary and Treasurer of the Association This list and the annual report of the Librarian for 1886, with a full index and title page for the volume, fill so many columns that we have but little space for other reading matter in this number As our next issue will constitute the first number of Volume X, now is a favorable time for new subscribers to send their orders for THE JOURNAL, and it is an equally favorable time for such old subscribers as are in arrears, to pay up And for all, whether new or old, we wish a *happy New Year*

ALCOHOLIC REMEDIES IN TYPHOID FEVER

A leading article in the *Medical News* of the 24th of December, 1887, in referring to "an outline of the modes of treatment in typhoid fever pursued at twelve of the chief hospitals of this country," says "The use of alcohol is recommended by all the writers, and we have, as yet, no substitute for it in the progressive asthenia of the disease" Before knowing how much value can be awarded to this apparently united testimony in favor of alcohol in typhoid fever, it would be necessary to know how many cases of the fever any one or all of the writers alluded to, have actually treated without alcohol, that they might have a fair basis of comparison of the results We have tried the experiment of treating typhoid fever and all other general fevers without using alcoholic remedies, both in hospital and private practice for thirty years, and have found no difficulty in finding better remedies for counteracting the asthenia of this fever, and obtaining a higher ratio of recoveries than has ever been obtained with its use With iodine as a general alterant and antiseptic to counteract the molecular degeneration in the tissues and the blood, and the choice of cardiac and vaso motor tonics from the class of remedies represented by digitalis, coffee, tea, strychnia, strophanthus, carbonate ammonia, camphor, etc, according to the special symptoms of each case, and vigilant attention to the local complications that are in many cases more dangerous to the patient than the general disease, with an equally vigilant attention to the proper administration of simple nourishment and pure air, we have no place or need for the use of alcohol as a remedy in these cases And of a considerable number of intelligent and active practitioners who have tried the same experiment, though for a less number of years, I have not yet found one who was not fully satisfied with the result

A B PALMER, M D, LL D, Dean of the department of Medicine and Surgery, and Professor of Pathology and Practice of Medicine in the University of Michigan, died on the evening of the 23d of December, 1887, aged 72 years By the death of Dr Palmer, the profession has lost one of its oldest and most honorable members A conscientious and skillful practitioner, an able writer, an earnest and successful teacher, and above all a most estimable citizen and Christian, for more than forty years he has filled an important place in the profession of this country One of the last prominent services he rendered the profession, was in ably discharging his duties as President of the Section of Pathology in the Ninth International Medical Congress, at Washington, D C, though in impaired health at that time Ripe in years and in fruitful labors, he has truly "entered into rest"

FRANK T ANDREWS, M A, M D, lecturer on Histology in the Chicago Medical College, has recently been appointed assistant physician in the gynecological department of the Mercy Hospital of Chicago

ADDITIONS TO THE LIBRARY FROM MAY 1, 1885, TO APRIL 29, 1886

Mr President —I have the honor to present the accompanying Catalogue of additions made to the Library of the Association by donations, exchanges and subscription during the past year The Catalogue shows that since my last report 232 distinct titles have been added, exclusive of a number of Transactions, Reports of Boards of Health and Medical Journals, foreign as well as domestic, not previously received and catalogued The average yearly increase of the Library from 1882 to 1885, the date of my last report, has been at the rate of about 120 distinct titles, so that there has been during the last year a gain of nearly 100 per cent in new titles The Library now contains 2491 titles, representing about 7030 volumes Owing to the absence of funds for binding, there are at present about 300 unbound volumes of periodicals, transactions, etc, on the shelves of the Library

Respectfully submitted,
C H A KLEINSCHMIDT, *Librarian*

BOOK REVIEWS.

TREATISE ON HUMAN PHYSIOLOGY For the use of Students and Practitioners of Medicine By HENRY C CHAPMAN, M D, Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia, etc, 8vo, pp xv—945 Philadelphia Lea Brothers & Co 1887 Chicago A C McClurg & Co

With the works of Dalton, Flint, Foster and Landois and Stirling in reach of the student and practitioner of medicine whose linguistic attainments go no farther than the English language, not to mention other works, one may well be surprised that one whose time is not wholly given up to physiological work "should feel it incumbent upon himself" to write a book on physiology The author of the work under consideration, after an experience of eight years as a professor of physiology, became convinced that students and practitioners of medicine feel the want—which is to say, the lack or absence—of a systematic work on physiology, based on comparative and pathological anatomy, clinical

medicine, physics, and chemistry, as well as upon experimental research If this be the ground upon which the book was written—the lack of such a work on physiology—then the author has not labored wisely, since no such want exists nor has existed since the appearance of Sterling's translation of Landois's masterly work two years ago, not to mention other good works on physiology

But while the author's excuse, or reason, for writing his book has no foundation in fact, the work is a good and acceptable one It is a safe work to place in the hands of a student, and it is a very readable book It would have been much less painful to the eyes of readers had the sheets been corrected by some one acquainted with French, Italian and German words and names The foot notes of the book bristle with mis spelled words and incorrect titles There is too much of such carelessness in our publications

As to the matter of Dr Chapman's book, it must be said unhesitatingly that it is good In reading it one is often reminded, by the style, of the lecture room the style is easy, and by its ease many pages of physiology, that must otherwise be rather dry, are made interesting The book does not need the author's apology for having written it As a matter of fact it is surprising that the author has written so good a book after so short an experience as a teacher

ANATOMY, DESCRIPTIVE AND SURGICAL By HENRY GRAY, F R S , etc The Drawings by H V CARTER, M D , etc , with additional drawings in later editions Edited by T PICKERING PICK A new American from the Eleventh English Edition Thoroughly revised and re edited by WILLIAM W KEEN, M D , etc , to which is added Landmarks, Medical and Surgical, by LUTHER HOLDEN, F R C S , with additions by WILLIAM W KEEN, M D 8vo, pp 1,100 Philadelphia Lea Brothers & Co 1887 Chicago A C McClurg & Co

The above is a copy of a portion of the title page of the last edition of the most popular work on anatomy ever written It is sufficient to say of it that this edition, thanks to its American editor, surpasses all other editions It is not the "Gray's Anatomy" of ten years ago The student of that day would scarcely recognize it, with the large number of new illustrations, the careful change of much of the text for the better, and the many colored illustrations With such a work in his hands the student can no longer complain that "anatomy is dry bones "

TEXT-BOOK OF THERAPEUTICS AND MATERIA MEDICA Intended for the Use of Students and Practitioners By ROBERT J EDES, A B , M D pp 532 Philadelphia Lea Brothers & Co 1887 Chicago A C McClurg & Co

The book before us is well printed and bound, and of convenient size We have, however, been disappointed at the brevity of the description of the physiological action of many drugs, even of very important ones This work must be looked upon rather as a brief handbook than as an exhaustive treatise It certainly cannot replace H C Wood's well known text book It is written in a pleasing, readable style, and so arranged that reference can be readily made to any subject

MISCELLANEOUS.

HEALTH IN MICHIGAN —For the month of November, 1887, compared with the preceding month, the reports indicate that pneumonia and erysipelas increased, and that typho malarial fever remittent fever, diarrhœa, dysentery, intermittent fever, and cholera morbus decreased in prevalence Compared with the preceding month the temperature in the month of November 1887, was considerably lower the absolute humidity and the day and the night ozone were considerably less, and the relative humidity was slightly more Compared with the average for the month of November in the nine years, 1879–1887, intermittent fever, typho malarial fever, consumption of lungs, remittent fever and diphtheria were less prevalent in November, 1887 For the month of November, 1887, compared with the average for corresponding months in the nine years, 1879–1887, the temperature was about the same, the absolute and the relative humidity were slightly less and the day and the night ozone were less

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of November, 1887, at 63 places, scarlet fever at 36 places, typhoid fever at 39 places and measles at 18 places Reports from all sources show diphtheria at 5 places more, scarlet fever at the same number of places, typhoid fever at six places less, and measles at six places more in the month of November, 1887, than in the preceding month

A DECISION AS TO COSTS IN SUITS FOR MALPRACTICE —For a considerable time a suit has been pending against a physician of Boston founded on a charge of malpractice involving some operative procedure for removal of the ovaries It has been tried four times The first three trials resulted in disagreement of the juries The fourth trial recently terminated in a verdict for the defendant But the item of most interest to members of our profession is that, at the opening of the last trial, the counsel for the defense applied for and obtained a decision of the Court, that all the costs of the four trials should be paid by the plaintiff, in case the final verdict of the jury should be in favor of the defendant The example thus furnished in this trial is worthy of the careful consideration of all judges before whom charges of malpractice are brought, a large proportion of which have no other foundation than a desire to extort money from the defendant sufficient to secure a good fee for the prosecuting counsel

ALBERT B STRONG, A M , M D , for twelve years Demonstrator of Anatomy in Rush Medical College, and Lecturer on Anatomy in the Spring Course, has severed his connection with the institution by resignation At a full meeting of the students of the college, resolutions were adopted highly complimentary of his ability and faithfulness as a teacher of anatomy, and expressing their regret on account of his severing his connection with the college

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM DECEMBER 17 1887, TO DECEMBER 23 1887

Capt Victor Biart, Asst Surgeon, relieved from further duty in Dept Dakota S O 293, A G O , December 17, 1887
